TRIMMED BONELESS PRIMAL CUTS AND OTHER CARCASS CHARACTERISTICS OF SERIALLY SLAUGHTERED CATTLE OF TWO MATURE SIZES INDIVIDUALLY-FED CORN OR CORN SILAGE RATIONS IN TWO HOUSING TYPES

A.F.Y. Nour, M. L. Thonney, J. R. Stouffer and W. R. C. White, Jr. Cornell University, Ithaca, New York, 14853 U.S.A.

INTRODUCTION

The logical end points at which different breeds of cattle, under a specified set of management and environ-mental influences, produce desirable carcasses for specific markets may vary. By using regression and covariance analysis, serial slaughter offers an opportunity to choose a logical end point when assessing group or treatment effects on carcass characteristics (Berg et al., 1978). The objectives of this study were to examine effects of the energy density of the diet, bread type and the art that are a study were to examine effects of the energy density of the diet, breed type and housing regimen on carcass characteristics and yield attributes of cattle serially slaughtered over a range of 182 kilograms.

MATERIALS AND METHODS

Experimental design. Thirty-seven Angus calves from a herd of small mature size cows (approximately 400 kg mature weight) and 35 Holstein calves from many different dairy herds were used in this study to represent extremes in mature size. These cattle had USDA feeder calf grades of small frame, number 1 thickness, and large frame, number 2 thickness for Angus and Holstein, respectively. Average initial weights at the beginning of the experiment were 219.14 + 14.48 and 233.94 + 26.21 kg for Angus of the experiment were 219.14 + 14.48 and 233.94 + 26.31 kg for Angus and Holsteins, respectively. Cattle were randomly assigned within breed to inside individual pens or conventional lots with electronic feeding doors. They were ad Libitum fed either a high corn grain ration or a correction of the second sec They were ad *Libitum* fed either a high corn grain ration or a corn silage ration with appropriate supplements (Thompsy *et al.* 1980). Within each broad a distribution of a corn silage ratio with appropriate supplements (Thonney et al., 1980). Within each breed and across each ration and type of housing, cattle were slaughtered at five weights. Preassigned slaughter weights and the experimental design are in table 1.

Experimental procedure. When an animal reached its designated slaughter weight, it was held off feed and water for 18 hr prior to transport 15 miles to the abattoir. After clauster weight, it was held off feed and water of the state of the for 18 hr prior to transport 15 miles to the abattoir. After slaughter, the hot carcass weight (HCW) was obtained and carcasses were chilled at 19 C. Sover dove to the slaughter is a structure of the source of th tained and carcasses were chilled at 1° C. Seven days post slaughter, a randomly selected side (wholesale and side, WCS) from each carcass was quartered between the 12th and 12th at side, WCS) from each carcass was quartered between the 12th and 13th rib, as outlined by Wellington (1953) and Schoonover et al. (1967), with the modification that the saw out was not all others. Schoonover et al. (1967), with the modification that the saw cut was made through the upper 1/3 of the 12th thoracic vertebrae of the hanging carcass side. Carcass sides were scored for maturity and evaluated for marbing (intramuscular fat) on the exposed surface of the longitation that the saw cut was made through the upper 1/3 of the 12th long (intramuscular fat) on the exposed surface of the longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation that the saw cut was made through the upper 1/3 of the 12th longitation the upper 1/3 of the upper 1/3 of the 12th longitation the upper 1/3 of the upper 1 ling (intramuscular fat) on the exposed surface of the Longissimus m. by comparison with photographic standards (Wellington and Stouffer, 1959) and consensus of at least four appraison with photographic standards (Wellington and Stouffer, 1959) and consensus of at least four appraisers who also estimated the percentage kid ney, pelvic and heart fat (EKPH). Quality and vield grades were colority in also estimated the percentage and ards ney, pelvic and heart fat (EKPH). Quality and yield grades were calculated according to USDA official standards for beef carcasses (Carpenter et al., 1977).

Longissimus m. areas were traced and an average of three measurements was taken using an electronic graphic cal culator - planimeter (Numonic Corp., North West Pennsylvania) A single research using an electronic graphic tracks culator - planimeter (Numonic Corp., North West Pennsylvania). A single measurement of external fat thickness over the Longissimus m. was made. Wholesale cuts were separated fallowing over the Longissimus m. was made. Wholesale cuts were separated following a procedure adapted from AMSA guides for beef carcass evaluation (Schoonover et al., 1967), and around interpret for beef carcass evaluation (Schoonover *et al.*, 1967), and grouped into primal (chuck, rib, loin and round) non-primal (brisket, shank, flank and plate) categories. Primal cuts were trimed to the structure trimed to the structure and the structure and the structure trimed to the structure and the structure at the structure and the structure at the struc non-primal (brisket, shank, flank and plate) categories. Primal cuts were trimmed to 1 cm external fat and TABLE 1. EXPERIMENTAL DESTON TABLE 1. EXPERIMENTAL DESIGN

weighed (TPC). The other side and the non-primal cuts for the other side are de non-primal cuts from the $WCS \stackrel{\text{def}}{=} \stackrel{\text{def}}{=}$ boned. Total bone of WCS was calculated using the formation of WCS was calculated using the formation of WCS was stend of the formation of the lated using the fractional content bone in deboned side. Non-primal bone bone was subtracted from total bone to provide art to provide primal cuts bone weight,

Statistical analysis. Analysis of covariance (Snedecor and Cochran, 1976) was used 1976) was used to partition variance of associated with the main effects of ration, breed ration, breed, location, their inter the ext a

actions and a weight covariate. Deviation from a common regression for each main effect was tested by the were included in the model. sum of squares method (Draper and Smith, 1966). Significant main effect deviations from common regression included in the model.

While dressing percentage is often used as an indicator of weight of carcass for a given live weight, we chose in carcass hot carcass weight on live weight. Hot carcass weight increase (ne carc) and the weight in the carcass weight increase (ne carc) and the weight in the carcass weight increase (ne carc) and the weight (ne carc) to regress hot carcass weight on live weight. Hot carcass weight increased (P<.005) .744 kg for each kg in $cho^{cho^{2}e}$ in shrunk live weight (table 2) and this relationship was independent of ration brood and in Althoughin shrunk live weight (table 2) and this relationship was independent of ration, breed and location. Although there was a significant (P<.05) ration by breed by location interaction. there was a significant (P<.05) ration by breed by location interaction, in any ration-location subclass in the same live weight (table 2 figure 1). in any cattle produced heavier carcasses at the same live weight (table 2, figure 1). Data in table 3 show that lots any breed-location subclass cattle fed grain produced heavier carcasses than cattle fed silage and that, breed-ration subclass cattle fed in confinement produced heavier carcasses than cattle fed silage and that, 100 The absolute difference between rations, breeds or locations dependent of the silage and The absolute difference between rations, breeds or locations depended, however, on the other subclasses, is depended in converse of the other subclasses in the other subclasses is a subclasses in the other subclasses is a subclasses in the other subclasses in the other subclasses is a subclasses in the other subclasses in the other subclasses is a subclasses in the other subclasses in the other subclasses is a subclasses in the other subclasses is a subclasses in the other subclasses in the other subclasses is a subclasses in the other subclasses in the other subclasses is a subclasses in the other difference between Angus and Holsteins is consistent with previous observations (Berg and Butterfield, Callow, 1961; Cole et al., 1965; Maiga, 1974; and Wellington, 1971) and may be a reflection primarily of differences in fatness intrinsic to differences in mature size between breader between breader of the reflection primarily of the reflection primaril ferences in fatness intrinsic to differences in mature size between breeds and to differences between rations and locations in energy available above maintenance and muscle depositions in the differences between rate Angus and locations in energy available above maintenance and muscle deposition. However, variations between ^{ratio}

Values for quality grade, fat thickness, ribeye area, EKPH and yield grade all increased (P<.005) as carcases side weight increased (table 2). Angus carcases graded 2/2 unit bickness and bickness bickness areases graded 2/2 unit bickness and bickness areases areas areas areas areas areases areas areases areas are side weight increased (table 2). Angus carcasses graded 2/3 unit higher than Holstein carcasses, but only the Angus and 5 Holsteins, all at the lightest slaughter weights, had marbling scores below the small degree, with observation that energy density of the diet had no influence on cucliate carcaster (construction) and the small degree. observation that energy density of the diet had no influence on quality grade (marbling) is consistent with

reports by Young and Kauffman (1978) and Radloff et al. (1972). However, Utley et al. (1975) observed more Marbling young and Kauffman (1978) and Radloff et al. (1972). However, Utley et al. (1975) observed more Marbling in carcasses from cattle finished on a higher energy diet. Longissimus m. area increased (P<.005) .196 H_{01} stein carcasses in cold side weight (table 2). Angus carcasses measured 5 cm² greater (P<.005) than H_{01} stein carcasses in cold side weight (table 2). H_{olstein} carcasses at the same weight. This is in agreement with Maiga (1974) and Wellington (1971). TABLE 2. MEAN

nificant (P<.01) influence on fat thickness in young growing animals, but breed and level of energy intake had a synificant of the fattering phase $\gamma_{ield}^{iiicant}$ (P<.01) influence on fat thickness $\gamma_{ield}^{iiiicant}$ effect during the fattening phase.

Yield grade increased 0.025 unit/kg increase in side weight. There was no ration or location effect. However, Molsteins bad by the fattening phase. Molsteins at any given cold side weight. Thus, tope ins bad by the fattening of retail meat from high priced cuts, which supports the conclusions of $c_{olsteins}^{rolsteins}$ had higher expected yield of retail meat from high priced cuts, which supports the conclusions of r_{ols}^{rols} et al. (1965), Sim (1975) and Wellington (1971).

Figure 2 al. (1965), Sim (1975) and Wellington (1971). kg for each kg increase in cold side weight (table 2). Holsteins had 8.92 kg more (P<.1) PC than Angus steers breeds. This is in agreement with the findings of Dikeman *et al.* (1977) for Holsteins vs heavy British beef breeds.

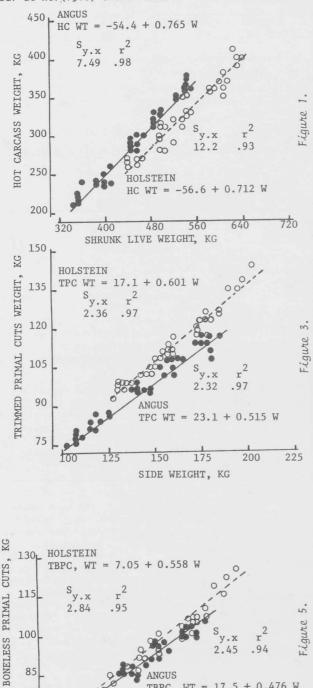

0

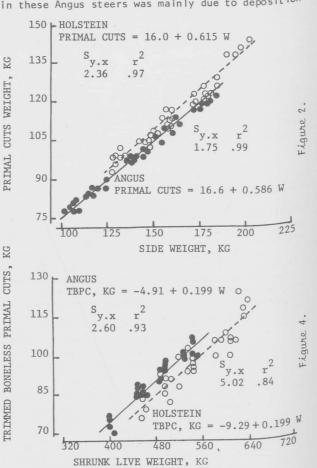

(uitingh (1962) observed lower proportions for most of what was considered in this study as primal cuts (shoulder, builtingh (1962) observed lower proportions for most of what was considered in this study as primal cuts (shoulder, bottom and the correspondence of the fattened steers than unfattened steers in beef cattle. From chuck (1962) observed lower proportions for most of what was considered in this study as primar cuts (including the study bettom, and rump) in the carcasses of the fattened steers than unfattened steers in beef cattle. From carcassh's (loca) is the carcasses of the fattened study, it is suggested that Angus produced more hot $t_{u_1t_1}^{u_1c_k}$, $t_1^{u_1c_k}$, $t_1^{$ $c_{rease}^{(rcass)}$ (1962) observations and the findings of this study, it is bugged as weight and had greater fat content (Nour *et al.*, 1980) than Holstein steers. This was expected to the strage the Proportion of PC, but on the contrary, it was reflected in lower weights of PC probably because the N_{0n} fat was defined by Luitingh (1962). ease weight and had greater fat content (Nour et al., extra fat was deposited in other parts of the carcass as observed by Luitingh (1962).

⁴ fat was deposited in other parts of the carcass as observed by Luitingh (1902). ¹⁰ Primal cuts (NPC) increased (P<.005) .308 kg for each kilogram increase in cold side weight (table 2). Al-¹⁰ side at light (NPC) increased (P<.005) .308 kg for each kilogram increase in cold side weight (table 2). Al-¹⁰ Side at light (NPC) increased (P<.005) .308 kg for each kilogram increase in cold side weight (table 2). Al-^{vh}primal cuts (NPC) increased (P<.005) .308 kg for each kilogram increase in cold side weight (table 2). Side weight at lighter weights the yield of NPC was similar in the two breeds; in Angus it increased with increase for Angus eight at the vertice of the cost faster rate than in Holstein steers. The faster rate of increase for Side weight at lighter weights the yield of NPC was similar in the two breeds; in Angus it increased with increase for Angus could be a significantly (P<.005) faster rate than in Holstein steers. The faster rate of increase for Could be a significantly increase of fat primarily in the brisket, flank and plate. These findings are in Angus could be due to the deposition of fat primarily in the brisket, flank and plate. These findings are in

agreement with Luitingh (1962) who compared the yield of the ventral parts of the carcass (comparable parts to the NPC) in fattened and unfattened beef steers. He concluded that these parts, where fat was deposited, formed a significantly (P<.01) larger portion of the carcass in fattened that unfattened the unfattened the second that the second the se a significantly (P<.01) larger portion of the carcass in fattened than unfattened steers.

Nour et al. (1980) showed that the increase in rib weight in these Angus steers was mainly due to deposition of

fat, which even surpassed muscle growth at heavier weights. From these observations and the start at heavier weights. From these observations and the above mentioned discussion of rate of increase of NPC it could be that the of rate of increase of NPC, it could be concluded that the additional increment in carcase which was additional increment in carcass weight in Angus steers was deposited mainly as fat in the water in Angus steers body. deposited mainly as fat in the ventral parts of the body. Similar observations were the ventral parts of the body who Similar observations were reported by Luitingh $(1962)_{saster}^{pown}$ concluded that fattening beef steers resulted in a faster growth rate and greater increases. growth rate and greater increase in weight for those parts of the carcass that command the large the larg of the carcass that command the lowest price and the $^{\rm parst}$ demand.

Figure 3 illustrates the relationship between trimmed pri mal cuts (TPC) and cold side workt is the two states in mal cuts (TPC) and cold side weight in Angus and Holstein steers. TPC increased (PC OC) _____ steers. TPC increased (P<.05) .558 kg for each kg incr^{ease} in cold side weight (table 2). Moreover, neither breed, ration or location influenced the vield of TPC when SLW was the covariate, TPC differences favored Holsteins (* kg) in individual housing and Angus (+5.29 kg) in conventional housing.

TRIMMED kg for each kg increase in SLW (table 2). A three way ration-breed-location interaction significantly $(P^{2}, 005)$ influenced the yield of TBPC. However, at any given SLW. Angus produced many (teraction significantly $(P^{2}, 005)$ is all 12.00 kg for the grain-fed, to 5.96 kg for the silage-fed steers. For individually housed cattle, breed difference were 1.36 and 6.21 kg for grain and silage rations, respectively. Lower yield of TBPC from the side of the silage rations, respectively. were 1.36 and 6.21 kg for grain and silage rations, respectively. Lower yield of TBPC from live weight cimilar observations were reported by Simpfendorfer (1974).

TBPC, WT = 17.5 + 0.476 W

100

125

Figure 5 illustrates the relationship between trimmed boneless primal cuts (TBPC) and cold side weight the rate of growth of TBPC was .080 kg/kg cold side weight (P<.05) greater for Holstein than for Angus .476 kg for each kg increase in 7 doubtein than for Angus .476 kg for each kg increase . lighter weights, Angus and Holstein carcasses yielded similar amounts of TBPC, but with increasing weight, ses. Holsteins increased .556 kg and Angus .476 kg for each kg increase in 7 day postslaughter side weight (table 2).

266

Since no attempt was made in this study to trim the intermuscular fat from the TBPC, it could be argued that the weight of the product of c^{μ} (1976) suggested that the weight of the picture for actual yield of TBPC would be different. Truscott *et al.* (1976) suggested that the weight of intermuscular fat was similar at the same total fat weight for Friesian and Angus steers. This is consistent with a same total fat weight for Friesian and Angus steers. With observations of Dikeman *et al.* (1977). Therefore, with trimming of intermuscular fat, Holstein carcasses Would maintain their superior yield of TBPC.

These results suggest that packers should pay more for live Angus than live Holstein steers unless the non-TABLE 3. SUBCLASS DEVIATIONS FROM MEAN WITH SHRUNK LIVE WEIGHT AS COVARIATE

Response variable	Individ- ual	Conven- tional	Individ- ual	Conven- tional	Individ- ual	Conven- tional	Individ- ual	Conven- tional	
rimmed her i	18.11	16.95	14.51	9.71	-3.73	-16.79	-17.33	-18.77	
cut weight, kg	2.60	5.30	3.22	2.23	1.24	-6.70	-2.99	-3.74	

Arcass components fetch a good market price to compensate for lower yields. On the other hand, to a packer Who is only interested in the yield of trimmed primal cuts, this study suggests that carcasses from both breeds Would the primal cuts of the prima build result in similar yields of TPC. The retailer, however, is interested in carcasses that will yield more PC, TPC and TBPC. Holstein carcasses would be a better choice for retailers than Angus carcasses. LITERATURE CITED
