### Introduction

The structural and mechanical properties of meat have a considerable effect upon its organoleptical and technological qualities. It is assumed that a number of factors modify Modifying the fibrillar structure of the muscular tissue, such as natural maturation, <sup>mechanical</sup> handling, enzyme treatment, irradiation, etc., resulted in the improval of its structural and mechanical properties. One of the methods being more largely used in the industry to increase the tenderness of meat proved to be the application of protectude. of proteolytic enzymes of vegetable and microbial enzymes contributed to their increa $g_{ical}$  and economical advantages of the microbial enzymes contributed to their increa-sing utility economical advantages of the microbial enzymes contributed to their increasing utilization in the meat industry (5, 6, 7). As a result of this, we made it our task to lization in the meat industry (5, 6, 7). task to investigate the effect of the bacterial proteolytic enzyme preparation Mesenterine 11-11 obtained from Bacillus mesentericus - strain 11-11(8,12)on the structuand mechanical properties of mutton.

# Material and Methods

The present studies were carried out on the sacral part of m. longissimus taken from sheep's ent studies were carried out on the sacral part of m. longissimus taken from sheep's and after chilling sheep's carcasses in warm condition (2 hours after slaughtering) and after chilling and storage at +4°C (48 hours after slaughtering). The muscle from the right side of the animate at +4°C (48 hours after slaughtering). the animal carcass used as the test sample was injected with 0.35% enzyme solution in 2% solution to the sample weight. The left part in  $\frac{2\pi}{2\%}$  sodium chloride solution at a ratio of 10% to the sample weight. The left parts the multiple work injected with 2% sodium chloride solution of the muscle being used as controls were injected with 2% sodium chloride solution only, in the being used as controls were injected with 2% sodium chloride solution. only, in the same proportion to the sample weight. The test samples and the controls were pack the same proportion to the sample weight. were packed in polyethylene bags and stored at a temperature of  $+2^{\circ}$  to  $+4^{\circ}$ C. The indicate the polyethylene bags and stored at a temperature of  $+2^{\circ}$  to  $+4^{\circ}$ C. The packed in polyethylene bags and stored at a temperature of the structural and  $p_{astic f}$  such as tenderness of muscular tissue after Grau (9), and structural and plastic f plastic firmness (10, 11) were used to determine the effect of the bacterial enzyme preparation means (10, 11) were used to determine the effect of the bacterial enzyme. preparation Mesenterine 11-11 on the structural and mechanical properties of meat. Samples to be tested were taken from meat injected in chilled condition on 72, 96 <sup>144</sup> hours postmortem, as well as from meat injected in warm condition on 2, 96 and 144 hours postmortem, as well as from meat injected in chilled condition on 72, 96 and 144 hours postmortem, as well as from meat injected in chilled condition of 9-30 measu-rements works postmortem. The trials were carried out in triplicate while 9-30 measurements were made on various indices and the average values of the corresponding num-ber of more made on various indices and the average. ber of measurements were stated in the diagrams enclosed.

The experimental results and their analysis showed that the bacterial enzyme prepa-ration Mesontania 11 11 had a considerable effect upon the structural and mechaniration Mesenterine 11-11 had a considerable effect upon the structural and mechani-property property of the structural and mechanical properties of mutton treated either in warm or chilled condition. For instance, upon determining the tenderness after Grau it was established that the values repor-ted in the tenderness after Grau it apparent trend to increase since ted determining the tenderness after Grau it was established that the target since the the test samples for this index showed an apparent trend to increase since tenderne test samples for this most has already raised on 48 hours postmortem to the tenderness of enzyme-treated meat has already raised on 48 hours postmortem to the tenderness of enzyme-treated meat has already raised on the tenderness of 132% <sup>tenderness</sup> of enzyme-treated meat has already raised on 40 nours postmeters of the as compared to the initial value. The process of improving the tenderness of 15 muscul muscul and on 144 h postmortem reached to an increase of 15 the muscular tissue continued and on 144 h postmortem reached to an increase of 155% of relation to the initial value. The process of improving the tender to the initial value of the process of the pro in relation to the initial value. Meanwhile, within the initial 48 hours after slau-ghtering of the initial value. Meanwhile, within the initial 48 hours after slaughtering a process of worsening of the tenderness was observed in the untreated samples which corresponded to the occurrence of the rigor mortis process, then a  $s_{ijk}^{10V}$ process of increasing the tenderness was initiated and reached just about on 144 postmortem the initial value.

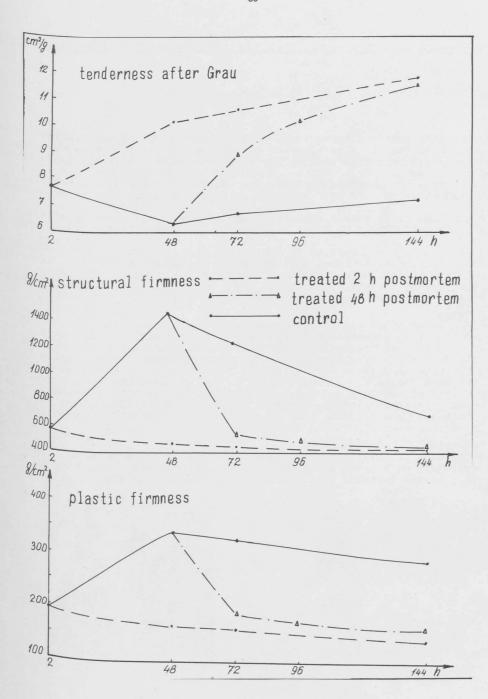

The results obtained from the determination of the structural firmness of the muse lar tissue indicated that the structural firmness was considerably increased in the controls on 48 h after yielding of most and then controls on 48 h after yielding of meat and then a process of decrease in the value for this index occurred but these values, however, remained higher than the initial ones on 144 h postmortem as well. ones on 144 h postmortem as well. A continuous, although comparatively slightly pronounced trend to decrease in the structural firmness of the muscular tissue was served in the enzyme-treated samples served in the enzyme-treated samples.

The values for the index of plastic firmness revealed the same important difference between the test samples and the controls. between the test samples and the controls. The plastic firmness continuously decree sed in the test samples while a drastic increase. sed in the test samples while a drastic increase occurred in the controls on 48 ms postmortem followed by a process of lowering in the plastic firmness; however, and the safter vielding of meet the untreated 144 hs after yielding of meat the untreated samples maintained considerably higher values for this index as compared to the samples maintained considerably higher to the samples maintained considerably high values for this index as compared to these of the enzyme-treated muscular tissue. Upon comparing the action of the enzyme preparation applied to warm and chilled it was established that the changes accurring the stablished that the stables accurring the stablished that the stables accurring the stables accurrence accurr it was established that the changes occurring in the structural and mechanical pro-perties of the meat material treated in shilled and the structural and mechanical properties of the meat material treated in chilled condition were identical in character to these reported for the samples treated in ter to these reported for the samples treated in warm condition. In the case of application of the enzyme preparation to warm most the plication of the enzyme preparation to warm meat, however, a considerably more active learned process of improving its structural and read active to be active to lerated process of improving its structural and mechanical properties was observed. In conclusion it should be suggested that an interview. In conclusion it should be suggested that an intensive increase in the tenderness and decrease in the structural and plactic firmers in the tenderness and decrease in the structural and plastic firmness of the muscular tissue were leted using the bacterial proteolytic enzyme preparation Mesenterine 11-11- From practical standpoint it appeared practical standpoint, it appears more expedient to apply the enzyme preparation warm meat thus creating conditions for the enzyme preparation improvin warm meat thus creating conditions for accelerated running of the processes improved the structural and mechanical properties and eccentric an the structural and mechanical properties and opportunities for savings in coldstores and energy consumption.
