SUMMARY

The effects of four diets prepared with several levels of barley (B), complemented with beet pulp (BP), cereals straw $(C^{S})^{0^{13}}$ hay (AH), [Diet 1 (%): 50 (B); O (BP); 14.3 (soy meal); 5.3 (CS) and 29.7 (AH). Diet 2: 0; 50; 14.3; 5.3 and 29.7. Diet 3: 30; 0; 11.1; 0 and 58 31 on the abaviant of the state of the sta 58.3. Diet 4: 15; 15; 11.1; 0 and 58.3], on the chemical and fatty acid (FA) composition of rabbit meat were studied.

Significant differences (p<0.05) were found for the chemical composition of the rabbit meat (n=10) for dry matter and fat in back to the provide the providet the provide the provide the with Diet 2 versus Diet 3 and for fat in batch fed with Diet 1 versus Diet 2. Significant differences (p<0.05) were also found for f_{out}^{for} 16:0, C-18:1, C-18:0 and C-20:4 free fatty acids in batch fed with Diet 2 versus Diet 2; Significant differences (p<0.05) were also found for complete versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:0 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:0 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 2 versus Diet 4; for C-16:1, C-16:0, and C-18:1 in versus Diet 4; for C-16:1 and C-18:0 in batch fed with Diet 2 versus Diet 1 and for C-16:1, C-16:0, and C-18:1 in batch fed with Diet 1 versus Diet 1 and for C-16:1 and C-18:0 in batch fed with Diet 1 versus

INTRODUCTION

Rabbit production for meat is a very important livestock activity in the most of Mediterranean countries. Likewise, in other could be applied and the second such as USA, New Zealand, Australia and some Asiatic countries, the rabbit meat industry is also very developed. The rabbits have a rapid of growth, a high feed efficiency, an early marketing age, and require a small land area (Cheeke, 1980). Moreover, in comparison with effects (Mfederer et al. 2000). Moreover, in comparison with effects (Mfederer et al. 2000). species, rabbits are able to consume large quantities of high-fibre feeds (Méndez *et al.*, 1986). This suggest that the rabbit has a practicular potential as a livestock species in large scale production. However, information on carcass quality and composition of rabbit meat is in the state of the state o contrast to that of other meats. Several studies have indicated that rabbit meat has high content of protein, but low levels of sodium and fill to the content of protein, but low levels of sodium and fill to the content of protein. *et al.*, 1978; El-Gammal *et al.*, 1984). It also possesses a relatively high content of phospholipids, ranging from 9% to 19% of 10% (Cambero *et al.*, 1991) and a relatively high content of a relatively high con (Cambero *et al.*, 1991) and a relatively high content of poliunsatured fatty acids (Ouhayoun, 1985). Thus, rabbit meat could be a interesting food in human dietetics interesting food in human dietetics.

Wa

A primary objective in rabbit production is to minimize nutrient requirements because their feed intake represents about 35^{56 of th} feed consumption in commercial farms. Moreover, an impairment in the composition of the diet has a great effect on meat composition. As an attempt to cheap the feed, several diets were prepared with four levels of barley, which were complemented with beilf

cereals straw or alfalfa hay. The effects of these diets on the chemical and fatty acid composition of meat were studied.

MATERIAL AND METHODS

During the first 20 days of life, the rabbits were fed exclusively with the milk from their mothers. From the 21st day to the end all rabbits were fed ad libitum with the appropriate diet. A pipele were in experiment, all rabbits were fed *ad libitum* with the appropriate diet. Animals were humanitary slaughtered at live weights ranging from 200

The formulation and the chemical composition of the diets are shown in Tables 1 and 2, respectively. Chemical composition of the diets are shown in Tables 1 and 2, respectively. Chemical composition of the diets are shown in Tables 1 and 2, respectively. was determinated according to AOAC (1980) methods.

For analysis, the animals were slaughtered and bled in a local abattoir. The head, viscera and skin were immediately removed, and was obtained removing the bones. The perirenal and subcutaneous for word, for was determined and subcutaneous for word. flesh was obtained removing the bones. The perirenal and subcutaneous fat was descarted. The meat obtained from each animal with minced in a blender (Sorvall, Omni-Mixer 17106). The final sample was common to fat the final sample was common to fat. minced in a blender (Sorvall, Omni-Mixer 17106). The final sample was composed of a homogenate of the meat from each animal. Same were kept at -20°C until analysis.

AOAC (1980) methods were used for the moisture (24.002), protein (24.057) and ash (24.009) determination.

(++): p<0.005; (+): p<0.05; (-): p≥0.05, not significant.

Gas-liquid chromatography (GLC) analysis of fatty acid methyl esters from fat of rabbit meat fed with the four experimental definition reveled the presence of more than twenty fatty acids. The more abundant ones are shown in Table 4. Although oleic acid is the most abundle fatty acid in most meats (beef, pork, mutton and chicken), the fat of rabbit is characterized by a high palmitic acid content, this always being major fatty acid (Table 4). This fact has been also observed by other authors (Chang-han and Yeon-Hee., 1982; Cambero *et al.*, 1991).

C-18:1 and C-16:1 were the monoenoic fatty acids most abundant (from 27 to 30% and from 5 to 7%, respectively). The percentage C-18:2 was about 15%, the C-18:3 concentration was, in general, lower than 1,5% and the C-20:4 was only found in a 0.5-0.9%. percentages have been reported by Matter (1981) and Cambero *et al.* (1991a). Tsimbakova *et al.*, (1979) observed that the levels of C-18:1 in rabbit fat varied from 1.5- to 5-fold lower than those of other meats.

(+++): p<0,0005; (++): p<0,005; (+): p<0,05; (-): p≥0,05, not significant

The effects of diet on fatty acid composition of rabbit meat have been studied by several authors, Ouhayoun *et al.* (1981) observed the incorporation of rapessed hulls to the rabbit diet produced a decrease in the concentration of saturated fatty acids (especially palmitic acid) and a small increase in polyunsaturated fatty acids of the rabbit perirenal fatty increasing incorporation of rapessed hull in the diet. Our results showed a slight increase of the C-18:0 content with increasing of crude for diet. Significant differences (p<0.05) were found between rabbits fed with experimental diets for many fatty acids (mainly C-16:1; C-16:1) and a with low 18:0; C-18:1), especially between rabbit fed with Diet 2 (complemented with 50% of beet pulp) and those fed with diets (1,3 and 4) with beet pulp percentage.

78

The effects of the diets used in this work on the physiology of rabbit are being simultaneously studied by other investigation team. The effects of the diets used in this work on the physiology of rabbit are being simultaneously used in the digestibility coefficient was higher as the beet pulp content increased in the diet. No significant differences were found when here the product of the physical sector of the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the digestibility coefficient was higher as the beet pulp content increased in the dincreased in the dincrea When barley was substituted for 15% beet pulp. At 50% beet pulp level, the growth rate of rabbit was delayed, and the carcass yield was lower García, personal communication).

In conclusion, it seems to be that barley may be substituted by beet pulp in the diets at levels up 15% without causing important adverse In conclusion, it seems to be that barley may be substantiated and fatty acids composition of rabbit meat.
