AMINO ACID ANALYSIS IN FRESH PORK AND DRY-CURED HAM BY HPLC OF PHENYLISOTHIOCYANATE DERIVATIVES

M-C ARISTOY and F. TOLDRÁ

Instituto de Agroquímica y Tecnología de Alimentos (C.S.I.C.), Jaime Roig 11, 46010 Valencia, Spain.

ABSTRACT

Substantial of the most important biochemical changes in ham during the dry-curing process consists in a natural increase in its free amino acids concentration. This increase may result in an enhance of the characteristic to the of dry-cured hams. ^{hagt}antial increase in its free amino actus ^{hat}ural characteristic taste of dry-cured hams.

has Precolum Phenylisothiocyanate (PITC) derivatization combined with reverse phase liquid chromatography chromatested for free amino acids analysis in muscle from both fresh pork and dry-cured ham. Preliminar The best decolum phenylisothiocyanate (PITC) derivatization combined with the set of the step of the step of the presence of an unidentificated peak coeluting with the arginine and taurine peaks. Furthermore, a some modifications which consisted in changes in column temperature (50 °C instead of 46 °C), pH of mobile step).

The 21 amino acids identified in meat were successfully separated and their quantitation completed. A fact, the increase in the free amino acid concentration along the dry-curing process has been detected. In proteial increases in glutamic acid (1368.6 vs 63.6 mg/100 g Protein), arginine (887.1 vs 84.2 mg/100 g Protein), alanine (1032.1 vs 198.8 mg/100 g Protein), valine (827.5 vs 50.5 mg/100 g Protein), leucine (937.0 mg/100 g Protein) and lysine (2008.6 vs 40.9 mg/100 g Protein).

INTRODUCTION

A characteristic texture and flavor are developed in hams during the dry-curing process. An intense ^A characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in name during for a characteristic texture and flavor are developed in texture and flavor are develo proteolytical changes in meat proteins and peptides are free amino acids which can have an important role in the file. the flavor (Kato et al, 1989). The conditions for free amino acids extraction from hams and sample deprotein. deproteinization have been already studied (Aristoy and Toldrá, 1991) but some problems remain in the ^{chromato} ^{chromato}graphic separation.

The objective of this study is the analysis of free amino acids in hams along a complete dry-curing set. The objective of this study is the analysis of file analysis of the precolumn phenylisothiocyanate derivatization method.

Supernatant was filtered through glass wool and ^{(deproteinic}) and ⁽¹⁾ and ⁽ deproteinized by adding 2.5 volumes of acetonitrile. After centrifugation (10,000 g, 5 min), the supernant was derivatized by adding 2.5 volumes of acetonitrile. After centrifugation (10,000 g, 5 mm,), ^{Used according to Bidlingmeyer et al (1987). Hydroxiproline, aminobutyric acid and norleucine were} ^{vati}zed according to Bidlingmeyer et al (1987). Hydroxiprofine, ^{ised as internal} standards in similar levels to those expected in the respective samples.

Chromatographic separation: Samples were analyzed in a 1050 Hewlett Packard liquid chromatograph equipped with a multiwayer a multiwavelength UV detector (254 nm). The column was a SupelcosilTM LC-18 DB, 250 x 4.6 mm (5um particle South ^{altiwavelength} UV detector (254 nm). The column was a SupelcosilTM LC-18 DB, 250 A transfer a separation: Samples Hold to ⁸^{ixe} protected with a LC-18 Pelliguard packed guard column (200 x 2.1 mm). The temperature was controlled to ^{50[±]lec</sub>}

6:2

Chromatographic conditions consisted of a solvent system of two eluents: (A) 0.14 M sodium $a^{cett^{4/4}}$ containing 0.5 ml/l of triethylamin (TEA) and adjusted to pH 6.75 with glacial acetic acid, and (B) $60^{c40/4}$ acetonitrile:water. To achieve the separation, the following flowrate and solvent composition gradient performed: Initial to 1 ml/min, 10%B; 6 min linear change to 0.8 ml/min and 12.5% B; 32 min linear to $50^{3/4}$ 33 min step to 1 ml/min and 100% B; wash for 8 min and reequilibrate at 10%B during 16 min before a main injection.

Chemical analysis: Protein contents in ham was determined by official Standard method based on Kjelith semimicro determination (Presidencia del Gobierno, 1979).

RESULTS AND DISCUSSION

A high variety of chromatographic conditions for the phenylthiocarbamyl free amino acid derivative separation have been reported in the literature (Ebert, 1986; Bidlingmeyer et al, 1987; Cohen and etrive 1988; Sarwar and Botting, 1990). These conditions mainly depend on the column and the kind of samples. some of these conditions were applied to analyze ham samples in a Supelcosil column, special difficuit appeared in the separation of two groups of peaks; one formed by arginine, taurine and an unknown peak and other by tryptophane, ornithine and a reagent peak. In order to optimize the separation, different in strength and pH of the aqueous solvent, gradient conditions and column temperature were assayed, conditions for an optimal separation were those described in the Materials and Methods section. A typic chromatogram of dry-cured ham is shown in figure 1. As can be observed, only 32 minutes are required for

Glutamine and taurine, which are two of the major amino acids in raw V_{gine} (2008.6 vs 40.9 mg/100 g Protein). ham, Were the only two slightly decreasing along the processing. According to table I, it seems that free the only two slightly decreasing along the processing. According to table I are the the the only two slightly decreasing along the processing. Were the only two slightly decreasing along the processing. According to table 1, this acids are continuously generated so that it is difficult to conclude which stage is most important for increas $t_{h_{i_8}}^{h_{i_8}}$ are continuously generated so that it is difficult to conclude which stage to make the shown to be active in the dryse. In any case, it is reasonable that muscle aminopeptidases, which have been shown to be active dryse. increase. In any case, it is reasonable that muscle aminopeptidases, which have been successful the dry-cured ham conditions (Toldrá et al, 1991), would have an important participation in the observed liberation of liberation of free amino acids.

CONCLUSIONS

^{Chromatographic} conditions for an optimal separation of phenylthiocarbamyl amino acids from raw and dry-^{curomatographic conserved} ham have been optimized.

There is a noticeable increase in the concentration of free amino acids along the processing of dry-cu^{re} ham, specially in glutamic acid, arginine, alanine, valine, leucine and lysine.
