^{Muence} of intramuscular fat (IMF) content on the eating quality of 29 porcine *M. longissimus dorsi* (LD) muscles was investigated. Varied from 0.5 to 3.0 %, while other factors which might affect the eating quality, such as pH₁, carcass weight, percentage ^{4 and internal light reflectance (FOP₂₄), were kept as constant and normal as possible. The eating quality was assessed four} ^{themal} light reflectance (FOP₂₄), were kept as contents of the last rip). ^{One posterior} (taken immediately ahead of the last rib) and one anterior (taken 16 cm ahead of the last rib).

^{bothe posterior} (taken immediately ahead of the last rib) and one americal (uncertained between the eating quality and IMF. Taking into ^{bothe wide} range in the IMF content, no positive relationship was obtained between the eating quality and IMF. Taking into the effect of the assessors with analysis of variance, the IMF content was found to affect tenderness. A higher IMF content did, $\int_{0}^{0} \int_{0}^{0} \int_{0$ p_{1}^{μ} p_{2}^{μ} p_{3}^{μ} p_{1}^{μ} p_{2}^{μ} p_{3}^{μ} p_{1}^{μ} p_{2}^{μ} p_{3}^{μ} p_{1}^{μ} p_{2}^{μ} p_{3}^{μ} p_{1}^{μ} p_{3}^{μ} p_{1}^{μ} p_{2}^{μ} p_{3}^{μ} p_{2}^{μ} p_{3}^{μ} p_{3}^{μ} p_{2}^{μ} p_{3}^{μ} p_{3}^{μ} p_{2}^{μ} p_{3}^{μ} p_{3 ^{Plece.} Of the investigated parameters, pH₂₄ had the greatest meters is that the anterior piece was more tender and ^{Vestent} (5.36-5.50). A lower pH-value gave a more tender meat. A notable result is that the anterior piece was more tender and h¹⁹ (5.36-5.50). A lower pH-value gave a more tender meat. A notable result to the second provide that the posterior piece, whereas juiciness did not differ in the two pieces. In conclusion, good eating quality in pork, which ^{b)} ^{c)} ⁽ⁿ⁾ ⁽ NOT DEPUTION

^{Acd and stored} at +4°C for three days. ^{Analysis:} The chemical composition was determined in a 4-cm section of the LD muscle removed at the last rib. The content of ^{Analysis:} The chemical composition was determined in a 4-cm section of the LD muscle removed at the last rib. The content of ^{Max} The chemical composition was determined in a 4-cm section of the LD muscle reasons (Stegeman, 1958 as modified by Nilsson, 1968), connective tissue (Stegeman, 1958 as modified by Nilsson, 1968), and ⁽¹⁹⁷³⁾, and water (Nilsson, 1969) were analysed.

Sensory analysis: At four days post-mortem, the pork loins were assessed by a 9-member taste panel. The LD muscle was divided to the sense of the se two different samples, one 8-cm section taken immediately ahead of the last rib and one 8-cm section taken 16 cm ahead of the last These two samples will henceforth be referred to as the posterior and anterior pieces, respectively. The anterior and posterior pleter assessed as two different samples, since it is known that the IMF content differs along the LD. The IMF content was estimated in the piece in accordance with a content to the transmission of the transmissio piece in accordance with a quadratic equation describing the IMF content at different positions along the LD (von Seth, unpublished results). 1.5-cm slices were find to a set of the set o results). 1.5-cm slices were fried 2 x 3 minutes (180 °C) to an internal temperature of 68°C and served immediately to the assessed Tenderness. flavour and iniciarcon a served immediately to the assessed and the served immediately to the served immediate Tenderness, flavour and juiciness were judged on a 9-point scale, where 1 = very tough, weak flavour and dry and 9 = very tender

<u>Statistical analysis:</u> Data was analysed with the SYSTAT program (SYSTAT, 1987) using Pearson correlation matrix, t-test and applied of variance. of variance.

Carcass and meat quality traits and chemical composition: Carcass and meat quality properties and the chemical composition of the loins are shown in Table 1 Table 1. Mean, maximum, minimum and standard deviation (std) for carcass and meat quality traits and the chemical composition of

	Lean %	Slaughter weight (kg)	pH ₁	pH24	FOP ₂₄	IMF % last rib	IMF % anterior	IMF % posterior	Conn. tissue %	75

4	2.00 - 2.49	2.17	9	2.22	2	
5	<u>></u> 2.50	2.89	3	2.62	2	

Sensory traits: Figure 1 shows the results of the sensory evaluation for the anterior and posterior pieces of the LD for the ⁵ different and full event of M^F end of M^F IMF-groups. The mean assessment of the tenderness, flavour and juiciness of the pork loins was more or less independent of IMF-free upper the pork loins used in this investigation were of good quality at The pork loins used in this investigation were of good quality, the mean values for tenderness, flavour and juiciness lying in the upper half of the scale. But, as shown by the large standard deviation. half of the scale. But, as shown by the large standard deviation, wide variations were noted between the assessors in the sensory evaluation (Figure 1). The anterior piece was significantly more tender than the posterior sample in IMF-groups 2, 3 and 4 and 10^{10} more the LD not depend on the variation in IMF content, which has often been argued to be the reason for variation in tenderness along the LD muscle. The flavour and juiciness were about the same interval. muscle. The flavour and juiciness were about the same in the anterior and posterior pieces. Considering the whole material, the case for piece obtained significantly higher scores in tenderness and flat piece obtained significantly higher scores in tenderness and flavour compared to the posterior sample. But this was not the case for juiciness.

Figure 4. The normalised influence of protein content on juiciness for the anterior piece of LD, (mean(min-max)=6.14(2.40-9.00)). of IMF, pH₂₄, percentage lean and protein content in the posterior piece of LD. (mean(min-max)=6.14(2.40-9.00)). of IMF, pH₂₄, percentage lean and protein content on junciness for the anterior piece of LD, (mean(min-max)=6.14(2.30-9.00)). Significant influence, $n \leq 0.001$; ***: $n \leq 0.01$; **: $n \leq 0.$

As shown by Figure 4, the juiciness in the anterior piece was only significantly affected by the protein content, and in a $n^{egative notion}$. The model explained 55 % of the total variation in the second seco The model explained 55 % of the total variation in juiciness. In the posterior piece, the percentage lean contributed much more load in a negative variation in juiciness. A higher percentage lean course and in a negative more load in the posterior piece, the percentage lean contributed much more load in the posterior piece. variation in juiciness. A higher percentage lean gave a more juicy meat. Furthermore, pH₂₄ and IMF contributed to a more juicy meat. whereas a higher protein content gave a less juicy meat. 57 % of the total variation in juiciness in the posterior piece was explained to a more this model. The flavour was not explained circuit. this model. The flavour was not explained significantly by any of the factors in the model, except for the assessors.

- The anterior piece of the LD was significantly more tender and had a significantly better flavour than the posterior piece of the sum is a muscle. The difference did not depend on the varieties is a final significantly better flavour than the posterior piece of the sum is a final significantly better flavour than the posterior piece of the sum is a final significantly better flavour than the posterior piece of the sum is a final significantly better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour than the posterior piece of the sum is a final significant better flavour the posterior piece of the sum is a final significant better flavour the posterior piece of the sum is a final significant better flavour the posterior piece of the sum is a final significant better flavour the posterior piece of the sum is a final significant better flavour the posterior piece of the sum is a final sis a muscle. The difference did not depend on the variation in IMF, since the samples were compared at the same IMF content. - Of the investigated parameters, pH₂₄ had the greatest influence on tenderness. A lower pH gave a more tender meat. IMF was found deteriorate the tenderness in the anterior
- Juiciness was affected negatively by the protein content. Moreover, percentage lean, pH₂₄ and IMF were found to affect juiciness
- The good eating quality of the pork used in this investigation, was maintained even at low IMF values, when cooked to 68 °C.
