# Predictive Microbiology: Targeted Control of Fermentation Processes A. Landvogt and B. Landvogt

NORDRECO AB, Box 520, S- 26700 Bjuv, Sweden

## Summary

In the production of dry sausage it is important to adjust the ripening conditions precisely to the selected starter culture, if optimum <sup>acidification</sup> performance has to be achieved. However, the effect of ripening parameters are not fully explained yet, and so far is has been impossible to achieve targeted control during the fermentation process. Therefore, a new concept of determining the acidification performance of starter cultures in dry sausage was developed.

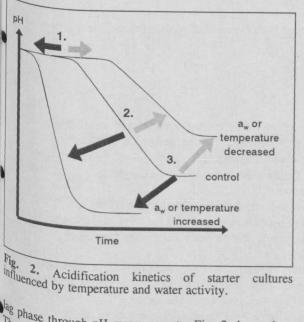

It is distinguished by chosen experimental conditions, which correspond largely to the conditions present during dry sausage ripening and thus provide results, that can be applied under practical conditions. The combined influence of temperature and water activity as ripening factors on the lag-phase and acidification capacity of different strains of Lactobacillus and Pediococcus was investigated.

By applying the modified linear Arrhenius model of DAVEY on the data it was possible to predict the combined effects of temperature and water activity on the acidification performance and the lag-phase. The model is easy to fit to data by using linear least squares regression procedure of nearly every spreadsheet. Therefore, the acidification performance during ripening can be predicted and influenced in a targeted way by means of a simple mathematical model.

## Introduction

Fig 1. Growth rate (A) and acidification rate (B) by a *Cactobacillus* starter culture (schematically).

Predictive microbiology focusses on investigations of models to predict the <sup>growth</sup> and death rates of food spoiling microorganisms or toxine production under variable environmental parameters [LEISTNER, <sup>1990</sup>]. Based on various multivariable experiments, mathematical models have been developed to predict shelflife and hygiene of food products if several parameters are influencing the microbiological growth at the same time, as it is present for foods. Predictive <sup>hicrobiology</sup> so far investigated mainly the growth behavior of food spoiling strains like Salmonella, Listeria and Staphylococcus

of microorganisms or the inactivation regimes (e.g. botulinum cook). These principles can not only predict growth rates but are also suitable to predict the growth of starter cultures. This is of particular interest, as during fermentations the physiological properties (ability to produce lactic acid) of the starter can be measured instead of the growth rate. Dry sausage ripening serves as a good example to varify the application

Mathematical models have been developed to describe either the growth

of the above model on a food product. During the ripening process starter cultures metabolize glucose to lactic acid. Besides many other parameters the acidification course strongly depends on temperature and water activity. It is therefore important to adjust the ripening conditions precisely to the needs of the starter culture to optimize the acidification performance (drop in pH/h). Here it is not only important to know the lag phase and the growth rate, it is essential to predict the influences on the metabolism (lactic acid production). The principles of predictive microbiology shall be extended to predict acidification performance.

Fig. 1 explains schematically the relationship between growth rate and acidification, as it can be expected with a Lactobacillus starter culture. Both shapes of the curves are similar but inverse and follow the same mathematical laws. Therefore it is possible to also determine the log and the

The area through pH measurements. Fig. 2 shows the general regime to be expected theoretically if temperature and a<sub>w</sub> are altered. The arrows point out three different effects. Primarily the lag phase is affected, secondly the acidification performance and thirdly the extend extend of the pH drop is changed. These relationships are common knowledge but have up to now not been quantified, especially if two  $h_{\text{fluencing}}^{\text{aud of the pH drop is changed.}}$  These relationships are common knowledge but have up to not not not determination don't provide these  $h_{\text{fluencing}}^{\text{aud of the pH drop is changed.}}$  These relationships are common knowledge but have up to not not determination don't provide these  $h_{\text{fluencing}}^{\text{aud of the pH drop is changed.}}$  are acting at the same time. Many methods of activity determination don't provide these  $h_{\text{fluencing}}^{\text{aud of the pH drop is changed.}}$  which are not comparable to  $\frac{1}{\log_{10}}$  mations, as they are usually carried out under quite different experimental conditions (e.g. substrate) which are not comparable to dry sausage ripening conditions.

## Material and Methods

To create a test which copies best the conditions during practical dry sausage ripening a model mixture of minced meat has been prepared. The batches with different aw have been inoculated with 3.107 CFU/g mixture starter culture. Lactobacillus curvatus 2. Lactobacillus curvatus 3, Pediococcus pentosaceus and Pediococcus acidilactici (Gewürzmüller, Stuttgart, Germany) have been used.

Adjustment of different aw values: 2,6% nitrite curing salt was added to each batch (except for aw=0.993). Different aw values were adjusted by adding increasing amounts of common salt. Glucose as a substrate for fermentation was added to a level of 1% to not limit the fermentation process. All starter cultures metabolized glucose. The temperature influence was tested in the range of 10, 15, 20, 25 and 30 °C.

Preparation of the batches: The chilled meat was minced all at once through a 2 mm hole plate. 500 g batches were adjusted to the appropriate aw as follows: nitrite curing salt, the right amount of common salt and glucose was made up to 500 g with meat and mixed in a mixer. 5 batches with 99 g mixture were prepared and inoculated with 1 ml of the starter culture. The microorganisms were care fully worked in by hand using disposable gloves. The mixture was evacuated to remove air inclusions and put in disposable plastic coll tainers closed with moisture impermeable lids. Measurements were taken until the pH had droped to its minimum value.

The acidification performance represents the pH drop per hour (-pH/h) and was calculated from the slope of a regression straight line approximated to the upper part of the acidification curve (Fig. 3). It includes the values from the end of the lag phase until a pH of 5.2 to 5.3 is reached. The length of the lag phase was obtained from the acidification curves (pH as a function of time) shown in Fig. 3 and 4, as the period from the start of the experiment (hour 0) to the beginning of the pH decrease. Further details are given in LANDVOGTAND FISCHER [1991 a, 1991 b].

DAVEY [1989] presented a predictive mathematical model to describe the additive effects of temperature and water activity during the growth phase. He applied his model on data collected from 7 publications and demonstrated that 92.9 ... 99 % of the data variation could be explained with this model (average 96.6 %). The model is derived from a linear Arrhenius equation with additional terms for the aw influences. In the present study the growth rate has been replaced by acidification performance ap (-pH/h) to adapt Davey's model.

$$\ln ap = C_0 + \frac{C_1}{T} + \frac{C_2}{T^2} + C_3 \cdot a_w + C_4 \cdot a_w^2$$
(1)

T = absolute temperature. Davey [1991] extended his model to describe also the lag phase changes. According to Davey,  $\ln (1/lag)$ time) is calculated with

ln (1 / lag time) = 
$$C_0 + \frac{C_1}{T} + \frac{C_2}{T^2} + C_3 \cdot a_w + C_4 \cdot a_w^2$$
 (2)

The goodness of fit is discribed by % variance. Because %V takes into account both the number of data (n) and the number of terms (N) in the model it is used in addition to the multiple regression coefficient (R<sup>2</sup>).

### **Results and Discussion**

Because of the comprehensive experimental design with 4 starter cultures tested at 5 different temperatures and 8 different  $a_w value^{5/2}$ 200 acidification curves with roughly 3000 readings have been evaluated. Fig. 3 shows the pH changes which L. curvatus 3 creates in batches with constant a of 0.962 but at different temperatures. This basic plot demonstrates already a recognizable influence of temperature on acidification. If the temperature drops from 30 °C to 10 °C the time necessary to reduce the pH to 5.2 increases from 17 to 210 hours. As expected the lag phase extends also with reduced temperature.

Fig. 4 demonstrates very well the influence of different water activities on the acidification. Comparable effects like in Fig. 1 call be observe here as well: decreasing aw increases the lag phase, the acidification performance drops and the level of minimum pH raises. The very fast acidification observed at  $a_w 0.993$  is not only determined by the high  $a_w$  but probably also by the absence of inhibiting not trite. trite.

This The acidification performance was calculated from the acidification kinetics as described above. Acidification performance, temper rature and water activity were then worked into the Davey equation (1) to calculate the values for  $C_1$  to  $C_4$ . The results are presented in Table 1. The variance values in Table 1 demonstrate how could be used the values for  $C_1$  to  $C_4$ . activ Table 1. The variance values in Tab. 1 demonstrate how good the model fits the measured data. The average % V = 0.969 is in the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's results applied to expect the transmission of the same range of DAVEV's same range of DAVEY's results applied to growth rates. These results are valid for a wide range of temperatures (10...30 °C) and average (0.002) As the results applied to growth rates. values (0.904...0.993). As the ranges chosen for temperature and  $a_w$  exceed values usually practised during dry sausage ripening, only the product further than the product of the model further than the product of the product temp

Table 1 also includes the results for the adaptation of the lag phase data of the individual starter cultures to the model. It has to be the form of the model or the model o noted that in common with DAVEY [1991] the  $1/T^2$  term of the model equation (2) was not significant for these data, whereas the term aw<sup>2</sup> was significant and had to be included in the value between the term and had to be included in the value between the term are the term. d adjus term aw<sup>2</sup> was significant and had to be included in the calculation. The model fits comparably well to the lag phase results with a variance of 0.939.

As it is an empirical model, DAVEY could not offer any physiological interpretation for the significance for the regression more coefficients of Table 1. Nevertheless it should be understood that the coefficient values represent also the influence of other factorial are present during the test, like the substrate variation, the different lots of starter cultures, the transformed are present and an area of the substrate variation. present during the test, like the substrate variation, the different lots of starter cultures, the pH, nitrite curing salt etc. As LANDVOGT and the substrate variation performance is independent from the above the starter cultures. FISCHER [1991] showed, the acidification performance is independent from the glucose concentration and the degree of comminution, its analysis of starter cultures, the pH, nitrite curing salt etc. As LANDVOGI but depends on the inoculation count of the starter cultures. Higher counts reduce the lag phase and increase the acidification performance.

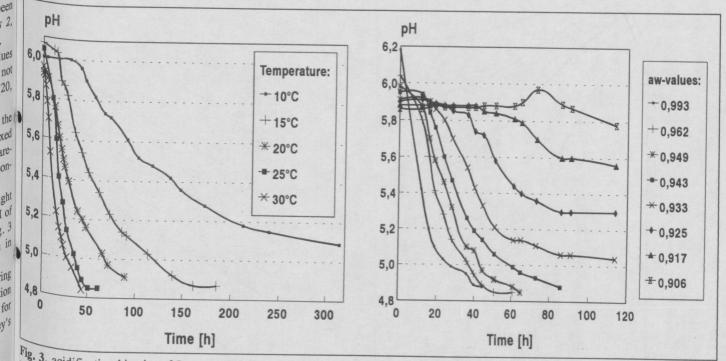

Fig. 3. acidification kinetics of L. curvatus 3 at  $a_w 0.962$  and various various temperatures. ()

Fig. 4. acidification kinetics of L. curvatus 3 at 25 °C and various water activities.

The kind of sugar (glucose, lactose, dextrines) will have an influence on the acidification performance but has not been tested here. In continous production processes such as dry sausage manufacturing, additional influence will stay uniform and will keep the coefficients of the model more constant. It is evident, that the water activity at 30 °C influences the acidification performance more that at 10 °C.  $^{\circ}C$ . At 30  $^{\circ}C$  the the slope of the curves at different  $a_{w}$  values is steeper than at 10  $^{\circ}C$ . Here the effect on acidification performance is  $al_{most}$  equally small for all starters. As the acidification performance is already low due to the low temperature, the low  $a_w$  value  $a_{most}$  value scarcely affects the process.

In most cases the substrate for starter cultures is very well known and standardized by the recipe. This allows to reproduce the same test conditions specially as the history of the substrate is known.

The kinetics of starters depend only on a few parameters of which most can be standardized by the recipe. For further investigation during industrial processing the influence of added spices, different sugars and combined starter preparations can be incorporated in the substrate to improve the reliability of the results.

## Conclusions

The principles and methods of predictive microbiology can be extended to starter cultures in addition to food spoiling microorganisms Instead of growth rates the fermentation product can be continuously measured which is a prerequisit to make targeted control possible for food fermentation.

As foods (instead of artificial growth media) are used as substrate, it is easier to transfer the results and validate them in commercial ally utilized processes. The combined influence of parameters can be analyzed.

An empirical mathematical model has been successfully applied to model the acidification of dry sausage; it can be included in a trol loop to control the acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a successful to acidification of dry sausage; it can be included in a su control loop to control the acidification performance by temperature. Additional applications for fermentation process as joghurt-, south dough-, Sauerkraut- and winemaking may be possible.
