PROPERTIES OF NON FERMENTED DRY SAUSAGE MANUFACTURED FROM BEEF AND LAMB MEATS WITH OR WITH-OUT SEASONINGS.

BRIAL M. ABU-SALEM, NAHED M. ABD ELMAGUID and E.I. SELEIM

Science and Dairy Department, National Research Centre, Dokki, Cairo, Egypt.

Sausage samples based on beef and lamb meats were manufactured in the form of non Sausage samples based on beef and lamb meats were manufactured in the previous meat sources were prepared with or without the presence of seasonings, i.e.lactose and glucose. Both of the manufactured sawage samples were prepared with or without ples were prepared with the prepa Mes were kept for ripening at room temperature for 21 days; through which changes that **Rere kept for ripening at room temperature for 21 days; through which changes courred in their chemical and physical constituents were considered. The investigated arameters include; pH value; percent of moisture, protein, fat lactic acid, carbohydrates, reight 1. Weight loss as well as peroxide value, content & nitrite and content of cured meat pigments. Statistical analysis of the results was considered within regression analysis and analysis of variance.

MTRODUCTION

Dry sausage could be manufacture from a wide range of meat sources. On the content was keeping qualities of such sausage depend upon curing ingredients, spices and removal of sture from the product by drying Anonymous, 1966; MacKenzie, 1966; Anonymous, 1968). It of improve that may attempt to speed the drying rate usually lead to a not-Dry sausage could be manufacture from a wide range of meat sources. On the other hand of important to mention that may attempt to speed the drying rate usually lead to a noticeable over drying of the surface of the sausage; a condition known as case hardening. This menomenon predludes any further attempt to remove moisture from the interior of the sausage. The roduction of sausage by the traditional method using aged salted meat requires nitrate as low being agent. On the other hand, the elimination of the use of nitrate in meat products is being agent. being considered all over the world by government agenties.

It is of interest to shed light upon the opinion of Zaika et al., 1976 who compared 200-1850 sausage containing Na NO₂(78-100 ppm) with other sample containing Na NO₃ 200-1850 ppm) from the view points of the changes in pH, titratable acidity and cured meat that low levels of Na NO₂(100 ppm) gave satisfactory, pigment. The available data proved that low levels of Na NO3(100 ppm) gave satisfactory, on the other hand, in some experiments with bolog The available data proved that low levels of Na NO₃(100 ppm) gave satisfactor, olor formation in the final products. On the other hand, in some experiments with bolog-las prepared with nitrate, considerable amounts of nitrite were found during the early stages of fermentation. For instance, after 4 days of fermentation, the nitrite concentration as less than 10 ppm.

Drying of sausages in the ripening rooms is usually achieved at 7.2-12.8°C, 70-72% development of sausages per hour; where they remain for several weeks to permit further development of the desired flavor, aroma and texture (MacKenzie, 1966). For economy, shortening the desired flavor, aroma and texture would be desirable so that the productions of the desired flavor of the desired flavor. tening the drying period of any given sausage samples would be desirable so that the product could be marketed in less time. The present work was undertaken to follow up some chemical physical states and lamb sausages during ripening for 21 days at room and be marketed in less time. The present work was undertaken to lollow up semble physical changes occurring in beef and lamb sausages during ripening for 21 days at room temperature. temperature. The available data was compared within statistical analysis. ATERIALS AND METHODS:

Materials:

Meat sources: About 40 kg of each of fresh beef and lamb meats were obtained after salanghter house, Cairo Governorate, EGYPT. The meat samples were grounded after at -18°C through on electric grinder using 6 in plate. Meat sources: About 40 kg of each of fresh beef and lamb meats were obtained from El

Technological methods:

Beef or lamb meat that previously grinded through a 6 in plate was mixed with 25% leat' aged for 48 h. at 4°C, and then regrinded through a 1.5 in plate. The individual aged samples samples to 15 kg batches and mixed with sodium nitrite, sodium ascorbate Reat aged for 48 h. at 4°C, and then regrinded through a 1.5 in.place. The individual samples were divided into 15 kg batches and mixed with sodium nitrite, sodium ascorbate with with Samples were divided into 15 kg batches and mixed with source in Table (1). with or without seasonings. (Lactose 0.6% and glucose 0.4%) as given in Table (1). Each batch was stuffed into the natural small sage samples were riped at room temperature for 21 days. Each batch was stuffed into the natural small intestine. Both of the manufactured

Methods:

Analytical methods: Moisture, fat content, nitrite (analyzed colorimetrically by according Griess reaction), peroxide values and protein (Kjeldahel N x 6.25) were determined at the AOAC (1985). Total carbohydrates were based on the phenol-sulphuric acid (Duboic Content of the AOAC (1985). hethod (Dubois et al., 1956). PH and titratable acidity were performed according to (Zaika,

Determination of meat pigments: Formation of cured meat pigments was followed by the Hornsey (1956) which was modified by (Zaika et al., 1976).

Normsey (1956) which was modified interesting to cured meat pigments% = $\frac{\text{nitrosyl-heme pigments(ppm)}}{\text{total heme pigments (ppm)}} \times 100 = \frac{\text{A}540 \text{nm}^{3}}{\text{A}640 \text{nm}^{3}} \times 100$

Statistical analysis: Multiple regression and analysis of variance for full regressing the carried out by the SAS computer program which was applied according to Helwig(1983) the 286 Parks of Agriculture of Agriculture and the Expire Parks of Agriculture of Agr Were carried out by the SAS computer program which was applied according to he was applied to he was applied to he was applied according to he was applied to he was ure, Ain Shams University. ESULTS AND DISCUSSION

The major chemical constituents (1) indicate the main following points: The major chemical constituents of the beef and lamb sausage samples that given in

There is a pronounced descending pattern in the moisture content as the ripening period. For instance, the moisture content of the beef sausage There is a pronounced descending pattern in the moisture content as a function of

containing seasonings that was 60.01% reached 29.52% after 21 days of ripening at room temp erature. This simply means that the moisture loss in the beef sausage within the aformention ned ripening period was 30.49% with a corresponding rate value of 0.7994.

- The rate of moisture decrement in lamb sausage containing seasoning ingredients was 0.7994. So, it is expected that moisture loss in beef sausage may occurs in a faster rate than the lamb sample. However, the correlation coefficient (R²) between moisture and ripening period was 97.09% for beef sausage "A" and 97.61% for lamb sausage "AA". The corresponding slope values were -1.4467 and -1.40186 ($\rm H_20\%/days$).

- When the protein content of the same samples was considered, the data of the same table showed no noticeable variations in its level during the whole ripening period in both

beef and lamb samples.

- With respect to the fat content of the same sample, the data of Table (2) showed the presence of higher "R2" values between the changes in fat content and ripening periods: being 93.45% in beef sausage "A" and 88.54% "AA" in lamb sausage. The slope of fat reduction was -0.0106 (fat%/day) for the former and -0.0094 (fat%/day) for the latter with a corresponding standard error of 0.0309 and 0.0376 as seen in the same Table.

The previous findings are in close to what had been reported by Lu and Townsend (1973) The percent of weight loss was given in Fig. (2) from which it was 28.75% in beef sausage "A" after 7 days of ripening and reached 43.65% after 21 days with a corresponding folding value of 1.5. Slope of weight hrs/day was 1.969 and the R² was 87.65% as seen in Table (3). In case of lamb sausage, the weight loss % of sample "AA" reached 42.51% by the end of 21 days of ripening which represents also about 1.5 folds of the weight loss % after 7 days of ripening. A similar pattern was noticed for other tested sausage samples; "B" and ""BB" as seen in "abla(2.4) However the abundance of the weight loss % after 7 days of ripening. A similar pattern was noticed for other tested sausage samples; "B" and ""BB" as seen in "abla(2.4) However the abundance of the weight loss % after 7 days of ripening. A similar pattern was noticed for other tested sausage samples; "B" and ""BB" as seen in "abla(2.4) However the abundance of the weight loss % after 10.5 % of the weigh "BB" as seen in Table(3,4). However, the shrinkage %, a trend which correlated with loss of moisture of the same investigated samples assured also the previous conclusion. Similar pattern of changes was noticed by Townsend et al. (1975). On the other hand, Uram et al. (1984) proved that the addition of emulsion to coarse ground smoked sausage eliminated the significant effect of grind size on total shrinkage. With respect to the changes occurre in the lactic residue of the changes occurre in the change of the changes occurred the the lactic acid content of the investigated sample; data given in Fig. (3) showed the following trends owing trends.

- There is a stepwise increase in the lactic acid content of beef or lamb sausage

during ripening periods.

- Such previous trend is differed within the tested samples. For instance, the inc remental level rate that was 1.3224 (lactic acid %/week) in beef sausage "A" reached only 1.1816 (lactic acid %/week) in beef sausage "B". The corresponding values in lamb sausage are 1.3326 and 1.1386 (lactic acid %/week) for the "AA" and "BB" samples respectively.

The increment of lactic acid may be related to the activity of lactic acid bacteria during ripening periods that extended for 21 days at room temperature. When the pH values of the tested sausages were considered, the data of Fig.(4) proved the presence of slight decoment by the starting of the day 14 with a slight further drop in pH values up to the end of the 21 days of ripening. Such trend could be related to the buffering capacity of the meat samples which resist or minimize the changes in pH values. It is a final trend to refer meat samples which resist or minimize the changes in pH values. It is of important to refer to the opinion of Wardlaw (1973) who proved that to the opinion of Wardlaw(1973) who proved that lactic acid content produced during fermentation of summer saugge remained a lactic lactic acid content produced during fermentation of summer saugge remained a lactic lactic lactic acid content produced during fermentation of summer saugge remained a lactic lac tation of summer sausage remained relatively constand (0.47-0.50%) from the end of fermental tion through 30 days of drying. The lactic acid quantity of 0.50-0.73% at 30-60 days is within the concentration range generally reported for summer sausage given by Acton, (1972).

The total carbohydrate content of the results o The total carbohydrate content of the sausage, samples under investigation that illustrated in Fig. (5) showed a down would be sausage, samples under investigation that illustrated in Fig.(5) showed a down word trend, a fact which could be related to one of the following reasons:

The activity of enzyme that breakdown the polysaccharides to simple forms.

Activity of microorganisms that consumed these simple sugars for their growth. However, the consumed % given in the same figure was higher in the presence of the added seasoning, i.e. lactose 0.6% and glucose 0.4% which may enhanced the activity of or ganisms during ripening. In such aspect, Ten Cate (1960) and Tandler (1963) proved that den attraction of salt soluble proteins during the cate (1960) and Tandler (1963) proved that aturation of salt soluble proteins during ripening of dry sausage is brought about by a decrease in pH due to the production of lactic acid by bacterial metabolism of carbohydra-

The cured meat pigments of beef and lamb sausages showed a shight improvement as in Figs.(6) and(7). The improvement rate level was 2.0054(% pigment/week) in beef sausage and 1.7457(% pigment/week) in the beef sausage The core of the cure of the cured meat. and 1.7457(% pigment/week)in the beef sausage B". In case of lamb sausage the rate of import vement level was 2.0314(% of pigment/week)and 1.7803(% of pigment/week)in batch "AA" and respectively. These results indicated the superiority of th respectively. These results indicated the superiority of the sausage samples that containing seasonings over the other one, i.e. no added seasonings. The aforementioned results are ing with Townsed et al., (1983) who found that conversion of total heme pigment to the nitric oxide heme pigment form was not affected by air changes during former total heme pigment to the method oxide heme pigment form was not affected by air changes during fermentation, but the method of fermentation did affect this conversion

of fermentation did affect this conversion.

Changes in peroxide values during the ripening periods of the same tested sausages are shown in Fig.(8). The pattern of the responsed data indicated a noticeable increment within the first 7 days of ripening after which a constant trend was approximatly realized to the end of the ripening periods. The constant trend was approximatly realized to the end of the ripening periods. The correlation coefficient of nitrite hydrolyses during periods was 93.78% in beef sausage "A" and 96.27% in beef sausage "B" as seen that the latter sausage "B" as seen the latter Table (3). So, nitrile hydrolysis is more pronounced in the latter sample than the former. To answer what is the tested parameters that highly correlated with ripening periods of the beef and lamb sausage, statistical analysis right. beef and lamb sausage, statistical analysis given in Tables (3,4)assured the periority of changes in lactic % and pu followed by changes in lactic % and pH followed by carbohydrates.

Moisture, proteins and fats of the investigated beef and lamb sausage samples were possidered through ripening periods that extended for 21 days at room temperature. Statiscal analysis proved the presence of higher (R²) in the moisture and fat changes during thening. The regression analysis and its analysis of variance of the responsed items namely the two sausage samples carbohydrate %, pH values, nitrite peroxide value, weight loss % igments and lactic acid content and were also given. Slope of regression in the beef saus-The showed a decline trend for the first three parameters, while the slope of the others showed a decline trend for the first three parameters, while the slope of regression of the cortesponding parameters showed a negative trend only for pH and a positive value for the other five parameters.
