EFFECTS OF FAT LEVEL, TAPIOCA STARCH AND WHEY PROTEIN ON FRANKFURTERS FORMULATED WITH 5 AND 12% FAT

E. Hughes, A. M. Mullen & D. J. Troy

Teagasc, The National Food Centre, Dunsinea, Castleknock, Dublin 15, Ireland

Key-words: Low-fat, frankfurter, tapioca starch, whey protein

Background/Objectives

Potential fat replacers in frankfurters include whey protein and tapioca starch. Whey protein has been used in a variety of meat products (Thompson, 1982; Ensor et al., 1987; Skrede, 1989; Chen & Ockerman, 1995; El-Magoli et al., 1995, 1996). However, none of the authors investigated the interactive effects of fat and the ingredient. Modified tapioca starch can improve flavour and reduce cook lossed (Knight & Perkin, 1991; McAuley & Mawson, 1994). However, to the authors' knowledge, no research has been published on its use in the hole of detailed to the second secon frankfurters. Given the lack of detailed studies on the effects of tapioca starch and whey protein on frankfurters, their effects on textural sensory and hydration/binding characterization. sensory and hydration/binding characteristics were investigated. In addition, the interactive effects of fat with the added ingredients were examined.

Materials and Methods

Six different frankfurter formulations were prepared in two separate trials according to Hughes *et al.* (1997). Two products were preparedcontaining 5 and 12% fat. Modified tapioca starch and whey protein concentrate were added separately to these emulsions at an addition reference added separately to these emulsions at an addition reference added separately to these emulsions at an addition reference added separately to these emulsions at an addition reference added separately to these emulsions at an addition reference added separately to these emulsions at an addition reference added separately to the second table and the second separately to the second separately to the second separately to the second separately to the second s of 3%. Two controls (5% and 12% fat) without the functional ingredients, were also formulated to give a total of 6 treatments (3 x 2 factorial design). For each product moisture, fat and motion design). For each product, moisture, fat and protein were determined (Bostian *et al.*, 1985; Sweeny & Rexford, 1987). Cook losses and emulsion stability were also recorded. Toxture profile and in (Bostian *et al.*, 1985; Sweeny & Rexford, 1987). emulsion stability were also recorded. Texture profile analysis (TPA) was applied to the cooked products based on a method described by Bourne (1978). An 8-member panel evaluated the sensory characteristics of the frankfurters. The trial was performed twice and the data from both was combined prior to statistical analysis. One-way analysis of variance (ANOVA) was carried out on the proximate data and the result of the remaining experiments were compared using two-way ANOVA with fat content and ingredient as factors. Interactions were considered significant when $D \leq 0.05$ significant when P<0.05.

Results and Discussion

Reducing the fat content increased cook losses and decreased emulsion stability. The addition of tapioca starch and whey protein improve both cook losses and emulsion stability. Other workers have also reported reduced cook losses from frankfurters with added whey protection of the stability of (Correia *et al.*, 1991; Ker & Toledo, 1992) but no comparative data is available for tapioca starch in frankfurters. Both tapioca starch in frankfurters. Both tapioca starch in frankfurters with added whey protein significantly altered the fat a water retire of the start in th whey protein significantly altered the fat : water ratio of the expressible fluid. Products containing tapioca starch released fluid with a high fat content compared with the controls. This implies that this ingredient is better at retaining water than fat in a meat batter. In contrast, protein apparently binds fat in the emulsion. The ANOVA indicated that there was a two-factor interaction between fat level and ingreduced for one of the hydration/binding characteristics are prior to the indicated that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that there was a two-factor interaction between fat level and ingreduced that t for one of the hydration/binding characteristics examined: tapioca starch has no effect on the volume of fluid expressed from produce containing 12% fat. When fat content was reduced to 5% attaction in the start of the start o containing 12% fat. When fat content was reduced to 5%, this ingredient reduced the amount of expressible fluid by approximately the lowest fat level of the amount of expressible fluid by approximately the This implies that tapioca starch works best at the lowest fat level when added water is high. Whey protein in contrast works well at both levels. levels.

Reducing the fat content decreased cohesiveness and gumminess of the frankfurters as measured by TPA (Table 1). The addition tanioca starch or when protein significantly investigation in the start of the frankfurters as measured by TPA (Table 1). either tapioca starch or whey protein significantly increased hardness, adhesiveness, gumminess and chewiness but had no effect springiness or cohesiveness. This is in agreement with previous studies which showed an increase in hardness and chewiness of knockwe with whey protein but no effect on cohesiveness (Ensor *et al.*, 1987). An increase in firmness was also noted in frankfurters with added with protein (Ker & Toledo, 1992). No interactive effects between first protein (Ker & Toledo, 1992). protein (Ker & Toledo, 1992). No interactive effects between fat content and ingredient were observed for any of the TPA values examined.

Table 1. Influence of fat, tapioca starch and whey protein on TPA values. Different letters in the same column (within each main effectindicate significant differences (P < 0.05). SL = Significance level. NS = Not significant.

The sensory characteristics of the frankfurters were affected by fat reduction (Table 2). Low-fat products were more smoky, more picy, more salty and had increased overall flavour intensity. Other studies have also shown an increase in spice (Yang et al., 1995; Hughes et al., 1995; Hughes $e^{t} a^{l}$, 1997) and smoke (Hughes *et al.*, 1997) intensities in low-fat frankfurters. Juiciness increased when fat content was decreased to 5%. Panellists were unable to detect differences in texture or acceptability between products regardless of fat content. The addition of whey protein Protein to the products did not significantly alter their flavour profile although tapioca starch increased the overall flavour intensity of the frankfurters. The latter may not be desirable in a low-fat meat product. It is known that reduced fat frankfurters release flavour compounds within the ^{more} rapidly than the higher fat products (Hughes *et al.*, 1997). Therefore, an ideal fat replacer should retain flavour compounds within the food matrix. ^{food} matrix and release them at a rate comparable to that of their full-fat counterparts. Using this criterion, tapioca starch may not be an effective and release them at a rate comparable to that of their full-fat counterparts. effective fat-replacer in low-fat frankfurters. The ANOVA indicated that there was a two-factor interaction between fat content and ingredient for two effective fat-replacer in low-fat frankfurters. The ANOVA indicated that there was a two-factor interaction between fat content and ingredient for two of the sensory parameters examined. Tapioca starch has no effect on spice intensity at 5% fat but at 12% fat the presence of the sensory parameters examined. Tapioca starch has no effect on spice intensity at 5% fat but is significantly ^{ingredient} significantly increased the spiciness. Similarly, juiciness is unaffected by the addition of tapioca starch at 5% fat but is significantly increased the spiciness. Similarly, juiciness is unaffected by the addition of tapioca starch at 5% fat but is significantly increased at 12% fat. This indicates that tapioca starch increases juiciness in products where added water is low and fat level is high compared with lower fat frankfurters with higher added water.

> Reducing the fat content significantly alters the hydration/binding properties of frankfurters. In addition, fat reduction increases the flavour interests of flavour release from the low-fat products (i.e., thensity of the products and alters their texture. Whey protein did not decrease the rate of flavour release from the low-fat products (i.e., havour intensities were unaffected). However, tapioca starch increased the flavour intensity of the 12% fat products above those of the control intensities were unaffected). However, tapioca starch increased the flavour intensity of the 12% fat products above those of the control intensities were unaffected). untensities were unaffected). However, tapioca starch increased the havour intensity of the table and products altered in the start and the st the texture of the products but these changes were not detected by trained panellists. The addition of tapioca starch and whey protein can advantage for low-fat meat products where navour release is increased and whey protein can advantage for low-fat meat products where navour release is increased and whey protein can advantage for low-fat meat products where navour release is increased and whey protein can advantage for low-fat meat products where navour release is increased and whey protein can advantage for low-fat meat products where navour release is increased and the products and the products advantage for low-fat meat products where navour release is increased and the products advantage for low-fat meat products where navour release is increased and the products advantage for low-fat meat products where navour release is increased and the products advantage for low-fat meat products where navour release is increased and the products advantage for low-fat meat products where navour release is increased and the products advantage for low-fat meat products where navour release is increased and the products advantage for low-fat meat products where navour release is increased and the products advantage for low-fat meat products ad Patially offset some of the changes that occur in low-fat products when fat is replaced with water. They improve emulsion stability, cook Osses and texture but their effects on flavour are minimal.
