Keywords: Beef, Texture measurement, muscles, ageing

Background and Objective: Mechanical texture measurements are in common use to evaluate effects of production and processing in ments on meat properties, to predict sensory tenderness, and to serve as a control parameter in quality assurance and certified programme wide range of different methods to study fundamental structure of meat are described and are useful for specific or general purposes. standard values for a generally acceptable tenderness are given and when comparison of results between laboratories or countries is desired well defined and standardised reference methods are accepted on the standard standardised reference methods are accepted on the standard stand well defined and standardised reference methods are required. One of the reference methods recommended by Chrystall et al. (1994) refers the probably most often used Warner-Bratzler shear test but with a modified blade.

In this work we compared an 'original' Warner-Bratzler shear device (Instron Ltd) with two modifications of this device and the Volodker's bite test in order to evaluate how these methods differentiate between the major texture compounds in beef - the myofibrils and the connect tissue - and how they correlate with sensory perception.

Material and Methods: M. longissimus dorsi (LD) and M. semitendinosus (ST) samples from 22 crossbred bulls were aged for both for 4th for 14 days at 2 °C to achieve variation in myofibrillar texture. The two different muscles accounted for variation in connective properties. The amount of collagen was 2.12 ±0.28 and 3.66 ±0.40 g/100 g dry matter in LD and ST, respectively. Heat-solubility of collagen was lower in ST compared to LD (12.0, 10.0) and 14.1, 19.7% was lower in ST compared to LD (12.9 ±1.9 % vs. 14.1 ±1.8 %). For mechanical texture measurements, 2.5 cm slices were vacuum-sealed PE-bags and cooked for 1 h at 72 °C in a water bath. The four mechanical devices compared are to be described as follows:

WBCOMMON	-	a 1.2 mm thick blade with semicircular edges and a 60° triangular hole running through a 2 mm slot. This must the 'original'
WBRECT.	-	warner Bratzler device delivered from Instron Ltd (Buckinghamshire, England). a blade with the same measures as WBCOMMON but with a rectangular 1x1 cm hole, similar to the device recommended by Christall et al. (1994).
WBBROAD	-	a 3 mm thick blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 3.8 mm slot blade with a 1x1 cm square edged, rectangular hole running through a 1x1 cm square edged, rectangular hole running through a 1x1 cm square edged, rectangular hole running through a 1x1 cm square edged, rectangular hole running through a 1x1 cm square edged, rectangular hole running through a 1x1 cm square edged, rectangular hole r

All devices were mounted to an Instron testing machine 4301. Blade and slot of the (modified) Warner-Bratzler devices were attached invertional apparents therefore were line in a slot of the (modified) warner-Bratzler devices were attached invertional apparents. compared to the original apparatus, therefore, working in compression. Crosshead speed was set to 200 mm/min for all devices. 1.27 cm cold (WBCOMMON) and 1 x 1 cm strips (all other methods) were taken parallel to fibre orientation from the cooked slices when they had cooledroom temperature. As previous findings in the same material indicated a systematic variation of texture properties over the cross-section of (Scheeder et al., 1995), three sections of equal texture properties were identified and one sample for each method was taken from each of three sections to avoid a confounding between event in a section of the sectio three sections to avoid a confounding between sampling position and method. Therefore, three replications were done per individual slice method. Respective cores and strips were cut perpendicular to fibres and maximum force (peak force) and overall energy required were

For sensory analysis, 2.5 cm slices were microwave cooked in a dish with pre-heated water to an internal temperature of 72 °C. 2 x 2 cm cub were served to six trained panellists who scored initial firmness, tenderness, and sustainable toughness on a 5-point scale (1 = very soft, 1008 or low, respectively; 5 = very firm, tender or high, respectively).

Statistical analysis was conducted using GLM-procedure of SAS (Vers. 6.04) with muscle, ageing and breed as fixed effects and all interactions included in the model. Deputies of the section of the sect actions included in the model. Panellists were additionally included as fixed effect, analysing sensory data.

Results and Discussion: The results given in table 1 show that peak force as well as energy of all mechanical methods discriminated between muscles and between ageing groups at a highly significant level. Therefore, sensory perception was well reflected. In terms of peak force while is the most common - and often the only recorded - parameter, the conventional method WBCOMMON achieved the highest F-values. Compare to sensory analysis, all Warner Bratzler derived methods discriminated ageing effect stronger than the effect of muscle resp. connective tist In all these methods, energy showed a response closely correlated with peak force. In contrast, VOLODKEVICH-peak force discriminated agent groups very well while VOLODKEVICH-energy differentiated best between muscles. This might be very useful when causal effects on me tenderness are to be evaluated, e.g. to separate effect of animal age and effects of technological factors like cooling rate. Regarding the level of the response, WBcommon showed the lowest values for peak force, despite the fact that the cross-section of the colling rate.

was about 0.267 cm² larger than that of the strips. This controversial finding might be explained by the more deforming cutting action of the triangular blade meeting the round core. The lavel of expression of the strips is a strip of the strips. triangular blade meeting the round core. The level of energy required was very similar for WBCOMMON and WBRECT. Due to the thickness of the WBRROAD blade the cutting occurred at two locations (University 1072) the WBBROAD blade, the cutting occurred at two locations (Voisey, 1976) resulting in higher peak force and energy compared to WBCOMMON

The completely different mode of working of VOLODKEVICH resulted in the highest peak force and the lowest energy values of all method compared. VOLODKEVICH-energy was the only of the recorded mechanical parameters giving higher values for ST/14-d compared to LD/4-0

Sustainable toughness	3.4	2.7	2.6	2.3	0.09	45.3	25.4

P < 0.01 corresponding to F > 6.95 for mechanical measures and F > 6.69 for sensory analysis

A specific relation of the initial impression of firmness to myofibrillar component and of the sustainable toughness to connective tissue was not found in this investigation to the expected extend. Overall tenderness discriminated both - muscle as well as ageing groups - as the best of all sensory texture parameters.

Overall correlation of all mechanical measures with sensory texture scores were high (Tab. 2), indicating that all mechanical methods used were sive giving a good index of meat tenderness. Nevertheless, it has to be considered that overall variability of the material used was also high.

Tab. 2: Correlations Between Mechanical Texture Measures and Sensory Judgement

	Peak force [N]				Energy [mJ]			
	WBCOMMON	WBRECT.	WBBROAD	VOLODKEVICH	WBCOMMON	WBRECT.	WBBROAD	VOLODKEVICH
litial firmness	0.70	0.71	0.68	0.70	0.70	0.74	0.68	0.61
enderness	-0.83	-0.84	-0.84	-0.82	-0.84	-0.86	-0.84	-0.75
ustainable toughness	0.81	0.84	0.82	0.82	0.82	0.85	0.83	0.73

^{correlations} were significant at p < 0.001

Conclusions: The results indicate that all compared devices gave a good estimate for meat tenderness. In discriminating between muscles or between the modifications with between ageing groups, the conventional Warner-Bratzler blade with a triangular hole performed slightly better than the modifications with quadratic holes. In comparison with sensory perception, all Warner-Bratzler derived devices were somewhat more sensitive to differences in ageing ageing dependent myofibrillar toughness than to connective tissue component of meat texture. The Volodkevich bite test gave the best r_{es} ponse on connective tissue toughness when using energy as a parameter.

 A_s results of all methods correlated well with sensory tenderness, factors like ease of handling and reproducible sampling as well as fabrication O_{fla} . of the instruments should be predominantly taken into account when developing a reference method or giving recommendations.
