are the second most common cause of bacterial food borne illness and pork is now recognised as one

seed borne sources of Salmonella (Berends et al. 1998, Belleville, 1998, B spp. are the second most end of the most important food borne sources of Salmonella (Berends et al., 1998; Beloeil et al., 2004). In the Republic of the most important food borne sources of salmonella (Berends et al., 1998; Beloeil et al., 2004). most important look octated on an on-going basis. Twenty four pigs from each herd are tested three times a year every pig herd is tested on a calculated weighted average of the the every pig netures to see a calculated weighted average of the three most recent tests. A most back are assigned a category (1-3) based on a calculated weighted average of the three most recent tests. A most back are assigned a category 1 ( $\leq$  10% positive) category 2 ( $\geq$  10%  $\leq$  50% and herds are assigned a category 1 ( $\leq$  10% positive), category 2 (> 10%;  $\leq$  50% positive) or category 3 herds are slaughtered separately from category 3 herds are slaughtered separately from category 3. onficate is issued grading.

At slaughter, pigs from category 3 herds are slaughtered separately from other pigs and in a manner while of contamination. While there is a considerable contamination. while there is a considerable amount of information available on the plantings the risk of salmonella in pork on the island of Ireland this has not been amalgamated and there are many gaps in urrence of Samonette in policy of a quantitative risk assessment approach to determine the contribution of essing to pork contamination during slaughter. This will involve a quantitative assessment of the contamination to policy containing to policy and risk factors contributing to its transmission via pork leading to an assessment of how and current controls are operating. To fill in key gaps in data needed for the exposure assessment, microbiological well current controls are pork will be conducted at pork plants and at retail level in the Republic of Ireland and some state of salmonetts in the Republic of Ireland and some state of the Republic of Ireland and Irela remain to hive signal and in pork cuts in both jurisdictions to be fed into a quantitative risk assessment This study reports the findings of the prevalence of Salmonella spp. in three commercial pork abattoirs in the Republic of Ireland.

## Materials and Methods

March 2006. To ensure that samples were representative of the factory throughput, the day on which sampling was carried out was altered during each sampling visit. A total of sixty samples from each oyster cut (primal leg cut) the taken over the entire working day, thirty in the morning and thirty in the afternoon. Sampling took place 2 hrs the work commenced. A 25-50g sample was excised from the oyster cut using a sterile scalpel and tweezers and transferred to sterile stomacher bags. Samples were transferred to a coolbox with ice packs and transported to the laboratory under chilled conditions 0-4°C. The method employed for the isolation and enumeration of Salmonella spp. to described in Figure 1.

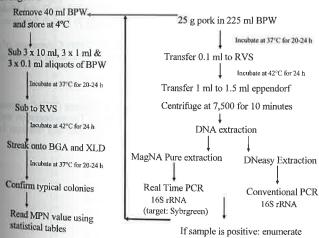

Figure 1: Schematic diagram of the method used to detect and enumerate Salmonella spp. in pork pieces in compation on the product that passed through the boning hall on the day of sampling i.e., slaughter date, number of suppliers and category of herd was obtained from each abattoir after each visit.

Results and Discussion

The number of samples positive for Salmonella spp. over two visits in each abattoir is shown in Table 1. In total 360 for the presence of Salmonella and 1.11% of these samples were found to be a sample when the presence of Salmonella and 1.11% of these samples were found to be a sample when the presence of Salmonella and 1.11% of these samples were found to be a sample when the presence of Salmonella and 1.11% of these samples were found to be a sample when the presence of Salmonella and 1.11% of these samples were found to be a sample when the presence of Salmonella and 1.11% of these samples were found to be a sample when the sample were found to be a sample when the presence of Salmonella and 1.11% of these samples were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample were found to be a sample when the sample when the sample when the sample were found to be a sample when the sample when the sample when the sample were sample when the sample when t The number of samples positive for Salmonella spp. over two visits in the samples were found to be possible samples were examined for the presence of Salmonella and 1.11% of these samples were found to be possible samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined in Abattoirs A or C. In abattoir A, the category of herd that passed through the samples were examined through the samples were examined to the samples were examples were example samples were examined for the presence of Samonella and A, the category of herd that passed through the best Salmonella was not recovered in Abattoirs A or C. In abattoir C, the category of herd that passed through the best of 2 colors to abattoir C. the category of herd that passed through the best of 2 colors to abattoir C. Salmonella was not recovered in Abattoirs A or C. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. In abattoir C, the category of herd that passed through the boning hall on each sampling day was 1 and 2 only. hall on each sampling day was 1 and 2 only. In abatton C, the category 3 as the supplier did not have 1, 2 and 3. However, further information revealed herds were classified as category 3. In abattoic p. 1, 2 and 3. However, further information revealed neros were category 3. In abattoir B, 4 of the certificate for these animals and therefore it is unknown if these animals were category 3. In abattoir B, 4 of the last certificate for these animals and therefore it is unknown if these animals were category 3. In abattoir B, 4 of the last certificate for these animals and therefore it is unknown if these animals were category 3. In abattoir B, 4 of the last certificate for these animals and therefore it is unknown if these animals were category 3. certificate for these animals and therefore it is unknown if the boning hall on the two samples taken during the boning hall on the two sampling days were all samples were positive for Salmonetta spp. These positive samples taken durin second visit. The category of herd that passed through the boning hall on the two sampling days was 1, 2 and 3 percentage of category 3 animals on the first and second sampling days was 17.0 and 9.0% respectively.

### Conclusions

In this present study, the incidence of *Salmonella* on pork cuts in the boning halls of the three abattoirs was LIPC. In has been reported that the prevalence of Salmonella on raw pork in the Republic of Ireland has decreased from 90 in 2000 to 2% in 2003 (Anon, 2004; 2005) and the results of this present study are in keeping with this trend. Future wark will increase the number of visits in each abattoir from two to five bringing the total number of samples analysed from 360 up to 900.
