Sustainable Food Systems

- Are protective and respectful of biodiversity and ecosystems; culturally acceptable, accessible, economically fair and affordable; nutritionally adequate, safe and healthy; while optimizing natural and human resources (FAO, 2010).
- Tradeoffs:
 - Energy dense foods often nutrient poor and less expensive
 - Nutrient rich foods/diets often have higher environmental impact – many are animal sourced foods.
 - Cultural preferences

Drewnowski et al. (2018) Front. Nutr. 4:74. doi: 10.3389/fnut.2017.00074

Lifecycle Assessment

An Introduction to a Systems Framework
for Evaluation of Alternate Solutions

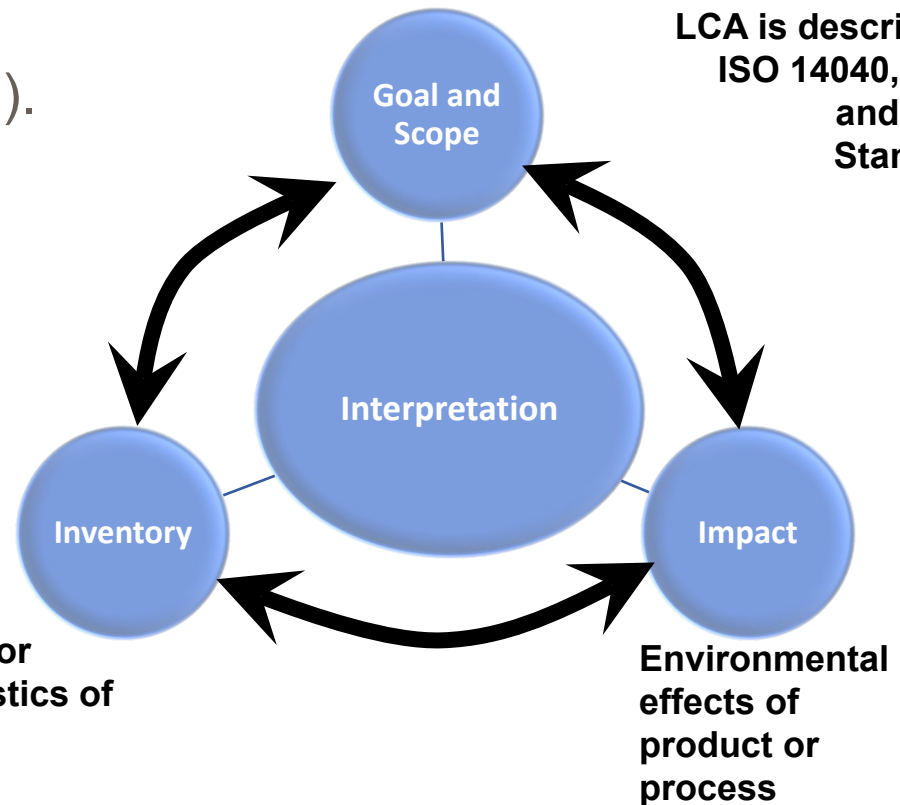

Lifecycle Assessment

Systematic quantification of inputs and outputs for a system in terms of a functional unit (FU).

- **Product Development / Improvement**
 - Selection of best materials or process options (e.g. conservation)
- Identification of 'hotspots' for innovation
- Benchmarking
- **Product labels / marketing**
- Strategic planning
- **Inform public policy**
- **Not: site assessment, EIA**
limitation of LCIA stage

**LCA is described in
ISO 14040, 14044
and 14046
Standards**

'Flavors' of LCA: attributional and consequential

An **attributional product system** is composed of:

- an **allocated share** of the activities that **have contributed** to production, consumption, and disposal of a product,
- tracing the contributing activities **backward** in time,
- Thus, data on specific or market **average** suppliers are relevant

Engineering
paradigm:
processes linked
physically

A **consequential product system** is composed of:

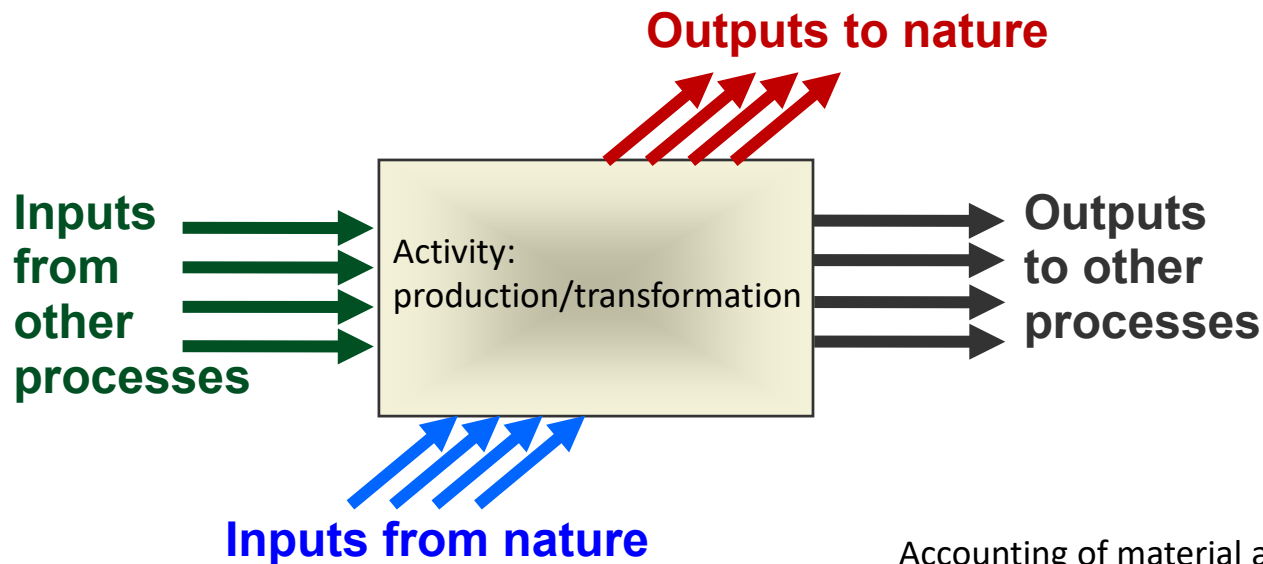

- the **full share** of those activities that **are expected to change** when producing, consuming, and disposing of a product,
- tracing the consequences of increased **demand forward** in time,
- Thus, data on **marginal** suppliers are relevant
(whose activity responds to change in demand)

Economic
paradigm:
processes linked
via *markets*

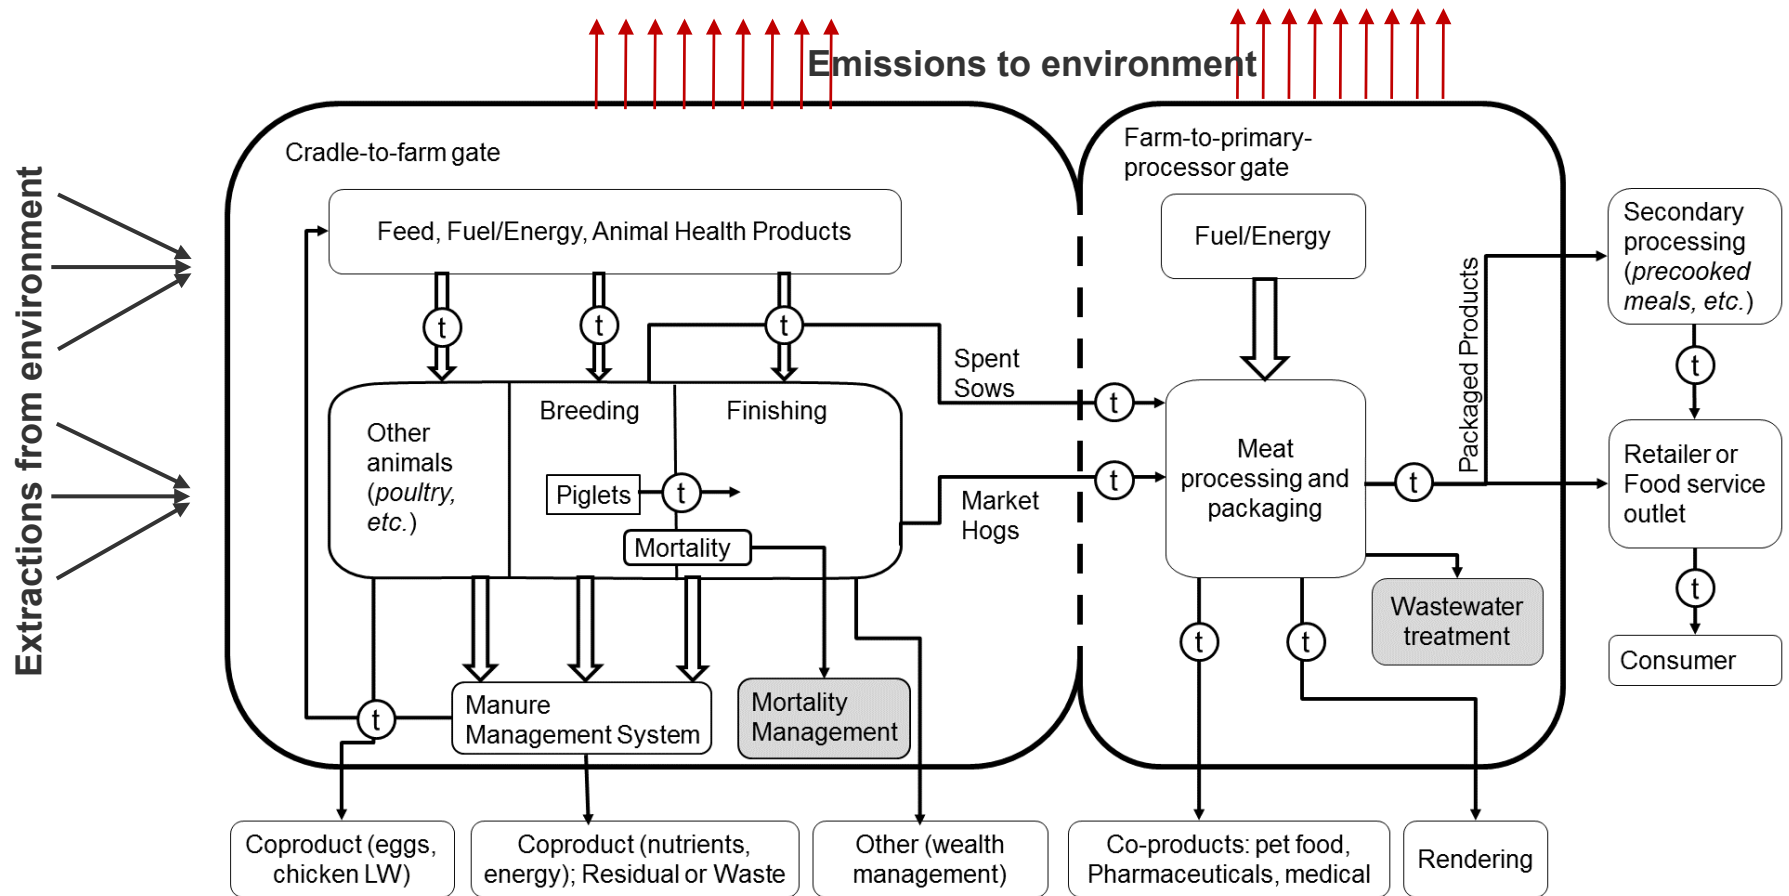

UNEP/SETAC (2011). Shonan LCA database guidance principles
Weidema, et al., 2018. Attributional or consequential Life Cycle
Assessment: A matter of social responsibility. J. Clean. Prod. 174, 305–314.

Unit processes: the building blocks of LCA (both flavors)

Life cycle inventory analysis:

system boundary with linked unit processes

What can LCA tell us now?

Environmental focus on production and consumption

Carbon Footprint of Milk

Large variation in existing system implies opportunity for sector level improvement without radical or disruptive technology advancement:

We can make progress in the near term.

Contribution analysis: Beef farm location matters

- Matched farm size and practices
Differences driven mainly by pasture-related emissions
 - Farm B pasture emits ~8X more N_2O per ha than Farm E
 - Pasture includes resource use associated with maintenance and emissions resulting from deposited manure and fertilizers

Adaptively Managed Paddock vs. Conventional Grazing

IFSM simulations of archetypical beef production in the Southeast. Both archetypes are Conventional Grazing (CG) Cow-Calf-Finish operations. NC is grain finished; VA is grass finished. The AMP alternatives were constructed by applying the low, average, and high carbon sequestration levels from Teague et al. (2017) on a per hectare basis, applied post-hoc to the archetype simulations.

Both farms produced approximately 250 kg CW (cull plus finished) per ha, and therefore the delta from AMP observed is similar for both.

EMISSIONS BY SOURCE

In million-tons of CH₄ per year (Tg CH₄ / yr), average 2003-2012

Anthropogenic fluxes Natural fluxes Natural and anthropogenic

Biogenic CH₄ ≠ Fossil CH₄

Biogenic CH₄ degrades to CO₂ and is then recycled through photosynthesis. Unless there is an increase in the **rate** of biogenic CH₄ emission, the net effect on the climate is neutral. The radiative forcing is driven by the concentration in the atmosphere while the GWP is calculated for each new 'puff' of CH₄.

All already agree that the climate change impact of respiration is zero!

Trends in Beef Biogenic Methane

“Falling short-lived climate pollutant (e.g. methane) emissions lead to falling global temperatures, while nominally “equivalent” CO₂ emissions, whether computed using GWP, global temperature-change potential (GTP) or any other conventional metric, would incorrectly suggest that these falling emissions would cause further warming.”

Challenges in LCA of food systems

- Data Availability – proxy & substitution can introduce error/ uncertainty
 - Incompatibility of sources, not all in public domain, extant data not always specific to food
 - LCI in agriculture often modeled (multiple models, variable predictions)
- Spatially Extensive – but LCA integrates the supply chain
 - Geospatially explicit LCI and LCIA in nascent stages
- Dynamic Systems – LCA is (generally) a static model
 - Is a static model still useful – yes, many situations.
- Impacts modeled – not benefits (evolving this direction)
- Incomplete metrics (in LCA framework)
 - Biodiversity, Ecosystem Services, Carbon Sequestration, Ocean Plastics, Soil Health, ***Nutrition***

Challenge of Incorporating Nutrition in the LCA framework

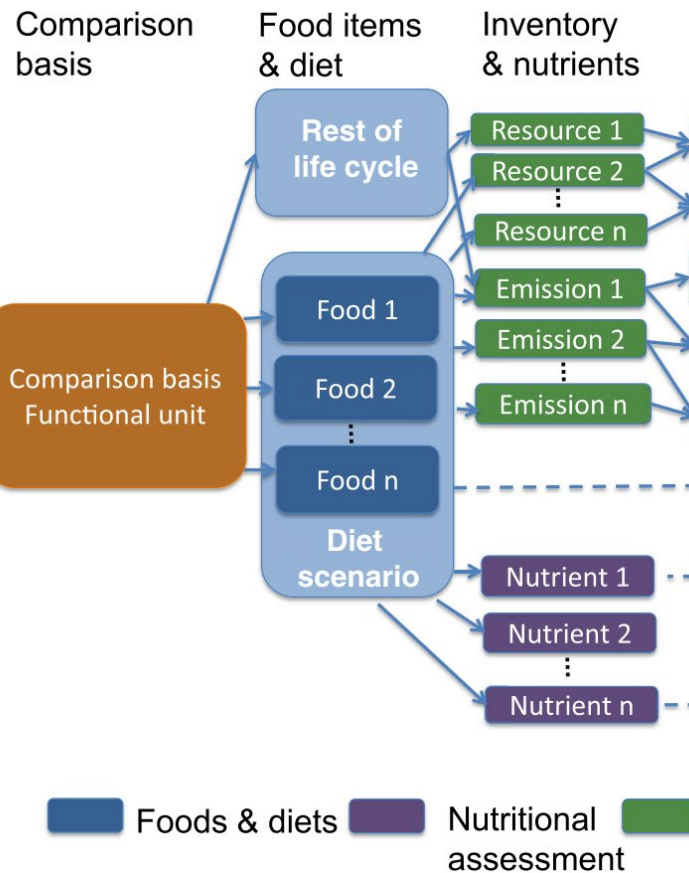

Drewnowski, A., et al., 2015. Am. J. Clin. Nutr. 101, 184–191.
DOI:10.3945/ajcn.114.092486

Incorporating Nutrition into LCA

- Impact or Function?
 - Nutrient content clearly a characteristic of foods – logical it be considered a functional characteristic
 - Comparison becomes problematic – how to get the same functional unit?
 - If nutrition effects are considered, then it is logical to consider the health impact in a conceptually similar manner to GHG emissions affecting climate
 - Comparison is less problematic – we can use a food, meal or diet as the functional unit
- NUTES
 - in development – based on RDA of 30 macro/micronutrients; no negative scores
- Nutrient Density/Indices
 - e.g., NRF9.3 and many others – accounts for beneficial and detrimental components of foods
- CONE LCA
 - Based on global burden of disease risks of NCD to assign DALY to food groups which can be summed with environmental DALY for a single human health impact score.
 - Relaxes the restrictions on functional unit (can now be a meal or diet).

Assessment needs: Data, metrics, integrated modeling

- Data should be transparent (to maximum extent feasible), validated, widely available, inexpensive. (e.g., NAL digital commons)
- Need for comparable metrics that span sectors, industries and geographies
 - Sustainability metrics should be science-based: life cycle assessment as system model supported by production, nutrition, economic and social components
- The same data and models should be used by producers, retailers, policymakers, NGOs and consumers.

Data	Production, processing, consumption, waste, disposal. Nutrient composition, dietary intake and link to health outcomes. Economics (cost, value added) of production and consumption chains: livelihoods and affordability; costs.
Metrics	Environmental footprints/index Affordability index Nutrient quality index (foods & diet); Safety and health outcomes (DALYs). Cultural and other choice restrictions
Integrated Modeling	Production (process/big data/statistical); Environment/health (LCA); Economic (GEM, PEM, LCC); Cultural/regulatory factors; effect of climate on production/nutrition => evaluation of alternatives, tradeoffs identified

Some benefits of ASF not fully accounted in most LCA

- Production on marginal land not suited for row crops.
- Upcycling of low-quality feed (food waste and byproducts – citrus pulp, almond hulls) to high-quality protein.
 - US ASF provide 24% of energy, 48% of protein approximately 50% of the essential amino acids and essential fatty acids as well as micronutrients (White and Hall, 2017).
- Micronutrient health benefits: Fe, Zn, B-12, Se
- Extensive production systems enhance ecosystem services; potential for C sequestration in grasslands.
- Livelihoods, wealth management, draught power, nutrition for developing world.

Sustainability Assessment of Animal Sourced Foods

- Ensuring that future generations can provide for themselves (both quantity and quality = nutrition security).
- Systems framework is necessary for capturing and interpreting measures and metrics and identifying trade offs to support informed decisions.
- Resources are beginning to constrain production:
 - We need measures and metrics to document and track progress and
 - Identify 'hotspots' and trade-offs for informed decisions/policy – everyone in the supply chain should be involved => team must include social scientists.
- More development of the benefits of ASF needed within the model framework: nutrition, ecosystem services, livelihoods.
- Linkage and integration of multiple models and tools is essential to drive improved outcomes: Social, Economic, Environmental and Health
